WO 2004/051222 A2

(54) Title: METHODS FOR THE IDENTIFICATION OF AGENTS FOR THE TREATMENT OF SEIZURES, NEUROLOGICAL DISEASES, ENDOCRINOPATHIES AND HORMONAL DISEASES

(57) Abstract: The present invention is drawn to methods of characterization of the properties and functions of SV2 proteins. The invention further includes methods of identifying compounds or agents which modulate the activity of SV2 proteins. Included in these methods is the identification of compounds or agents which modulate the binding of levetiracetam to SV2 proteins, including SV2A. Additionally, the present invention provides biotinylated ligands as a tool to screen chemical libraries and characterize the SV2 proteins. Further, the present invention provides a method of solubilizing and purifying functionally active membrane associated proteins, such as SV2.

**METHODS FOR THE IDENTIFICATION OF AGENTS FOR THE TREATMENT  
OF SEIZURES, NEUROLOGICAL DISEASES, ENDOCRINOPATHIES AND  
HORMONAL DISEASES**

5 **INVENTORS:** Berkley LYNCH, Karl NOCKA, and Bruno FUKS

**RELATED APPLICATIONS**

This application claims the benefit of U.S. Provisional Application 60/506,764, filed September 30, 2003, and U.S. Provisional Application 60/430,372, filed December 3, 2002, 10 which are herein incorporated by reference in their entirety.

**FIELD OF THE INVENTION**

The present invention is generally drawn to the field of drug discovery in neurological disorders, endocrinopathies and hormonal diseases.

15

**BACKGROUND OF THE INVENTION**

Neurological disorders afflict a substantial number of individuals and present an increasing economic challenge to health care systems since little is known regarding their causes, their diagnosis is often subjective, and many lack effective treatment. In general, 20 brain activity is ultimately determined by the capacity of neurons to communicate at synapses. Specific neurotransmitter chemicals are packaged in presynaptic neurons into synaptic vesicles which fuse with the presynaptic membrane to release *quanta* of the neurotransmitter chemical that traverse the synaptic cleft to activate the corresponding receptor type resident in the post-synaptic membrane. Among these receptor types are the 25 neuronal glutamate receptors (GluR's),  $\gamma$ -aminobutyric acid receptors (GABAR's), nicotinic acetylcholine receptors, serotonin receptors, dopamine receptors, and the like. Many neurological disorders are a result of improper conduction of electrical currents through synapses in various brain tissues. In epilepsy errant currents, hypothesized to be associated with improper function of synapses, cause various levels of seizures. Likewise, in several 30 psychiatric diseases, movement disorders and neurodegenerative diseases the conduction currents become aberrant, disorganized or reduced, thereby causing the disease condition.

Accordingly, defects in synaptic vesicle functions will have an adverse effect upon neurotransmission in general and control of neurotransmitter release in particular.

Seizures, including epileptic seizures, result from a focal or generalized disturbance of cortical function, which may be due to various cerebral or systemic disorders, including, for example, cerebral edema, cerebral hypoxia, cerebral trauma, central nervous system (CNS) infections, congenital or developmental brain defects, expanding brain lesions, hyperpyrexia, metabolic disturbances and the use of convulsive or toxic drugs. It is only when seizures recur at sporadic intervals and over the course of years (or indefinitely) that epilepsy is diagnosed.

Epilepsy is classified etiologically as symptomatic or idiopathic with seizure manifestations that fall into three general categories: 1) generalized tonic-clonic, 2) absence or petit mal, and 3) complex partial. Symptomatic classification indicates that a probable cause exists and a specific course of therapy to eliminate that cause may be tried, whereas idiopathic indicates that no obvious cause can be found and may be linked to unexplained genetic factors. Of the seizure categories, most persons have only one type of seizure, while about 30% have two or more types.

The risk of developing epilepsy is 1% from birth to age 20 yr. and 3% at age 75 yr. Idiopathic epilepsy generally begins between ages 2 and 14. Seizures before age 2 are usually caused by developmental defects, birth injuries, or a metabolic disease. Those beginning after age 25 may be secondary to cerebral trauma, tumors, or cerebrovascular disease, but 50% are of unknown etiology.

Due to the many interrelationships that exist between the nervous and endocrine systems, defects in synaptic vesicle function can also impact on endocrinological function. For instance, at least two glands secrete their hormones only in response to appropriate neurotransmitter release - the adrenal medulla and the posterior pituitary gland. Upon secretion, hormones are transported in the blood to cause physiologic actions at distant target tissues in the body. Obviously, endocrinopathies involving either hyper- or hyposecretion of hormones have pathological consequences. Exemplary of these consequences are gigantism and dwarfism, due to hyper- or hyposecretion of growth hormone, respectfully.

Levetiracetam

Levetiracetam (LEV; ucb L059; (*S*)- $\alpha$ -ethyl-oxo-pyrrolidine acetamide), the (*S*)-enantiomer of the ethyl analog of piracetam, was synthesized during a follow-up chemical program aimed at identifying a second-generation nootropic drug. *In vivo* results have demonstrated an unexpected potent ability of LEV to suppress seizures in the audiogenic-susceptible mouse, whereas piracetam was only weakly active. Although LEV is a molecule unrelated to established antiepileptic drugs (Margineanu *et al.*, in *Antiepileptic Drugs: 5th Edition*. pp. 419-427. Lippincott, Philadelphia (2002)), extensive clinical trials have proven that adjunctive therapy with LEV (KEPPRA, UCB, S.A., Braine-l'Allend, Belgium) is both effective and well tolerated in controlling refractory partial seizures in adults.

Binding assays with LEV, performed on crude rat brain membranes, reveal the existence of a reversible, saturable and stereoselective specific binding site. Results obtained in rat hippocampal membranes suggest that LEV labels a single class of binding sites with modest affinity and with a high binding capacity. This binding site is identified as the Levetiracetam Binding Site (LBS). Similar results have been obtained in other brain regions (cortex, cerebellum and striatum). Ucb L060, the (*R*)-enantiomer of levetiracetam, displays about 1000 times less affinity for these sites. The binding of LEV appears to be confined to membranes in the central nervous system since radiolabel studies could detect no specific binding in a range of peripheral tissues including heart, kidneys, spleen, pancreas, adrenals, lungs and liver. However, this could be due to a low density of LBS in these tissues compared to the central nervous system and indeed specific binding does occur in PC12 cells, a peripherally derived adrenal cell line.

The most commonly used antiepileptic drugs carbamazepine, phenytoin, valproate, felbamate, gabapentin, tiagabine, vigabatrin, zonisamide, phenobarbital and clonazepam, as well as the convulsant agent t-butylbicyclicophosphorothionate (TBPS), picrotoxin and bicuculline do not displace LEV binding (Gillard *et al.* *Eur. J. Pharmacol.* 478:1-9. (2003))). However, ethosuximide, pentobarbital, pentylenetetrazole and bemegride competed with LEV with pKi values comparable to active drug concentrations observed *in vivo*. Structurally related compounds, including piracetam and aniracetam, also displaced LEV binding. The levetiracetam analogues were also tested for their anticonvulsant activity in the audiogenic mouse model of epilepsy. A very good correlation ( $r^2=0.84$ ) was observed between the

affinity and the anticonvulsant activity (Noyer *et al.*, *Euro. J. Pharmacol.* 286:137-146. (1995)). This high degree of correlation is strong support for a causative relationship between LBS binding and anticonvulsant activity of this class of compounds. Accordingly, binding of levetiracetam analogues to LBS is expected to result in modification of the 5 function of the protein component(s) of the LBS in brain, leading to the desired therapeutic outcome of anticonvulsant activity.

### The Synaptic Vesicle Protein 2 Family

The Synaptic Vesicle Protein 2 (SV2) family of synaptic vesicle proteins was first 10 identified with a monoclonal antibody prepared against cholinergic vesicles from the electric organ of the marine ray *D. ommata* (Buckley *et al.*, *J. Cell Biol.* 100:1284-1294. (1985)). Cloning of the individual family members labeled by the antibody resulted in the 15 identification of three different isoforms, SV2A (Bajjalieh *et al.*, *Science*. 257:1271-1273. (1992)), SV2B (Feany *et al.*, *Cell*. 70(5):861-867. 1992) and SV2C (Janz and Sudhof, *Neuroscience* 94(4): 1279-1290. (1999)), all of which react with the original antibody. The overall homology between the three rat isoforms is approximately 60%, with SV2A and 20 SV2C being more similar to each other than SV2B (Janz and Sudhof, *Neuroscience* 94(4): 1279-1290. (1999)).

The SV2 proteins are integral membrane proteins and have significant but low-level 25 homology (20-30%) to the twelve transmembrane family of bacterial and fungal transporter proteins that transport sugar, citrate, and xenobiotics (Bajjalieh *et al.*, *Science*. 257:1271-1273. (1992)). As putative members of the 12 TM superfamily, SV2 proteins display several unique features. They have relatively short free N- and C- termini and short loops connecting the Tm segments. Two notable exceptions, however, are the long cytoplasmic loop between transmembrane regions 6 and 7 and the intravesicular loop between transmembrane regions 7 and 8 (which contains 3 N-glycosylation sites). No close homologs of the SV2 proteins have yet been discovered in yeast or invertebrates, although a distantly related synaptic vesicle protein known as SVOP does have homologs in *Drosophila* and *C. elegans* (Janz *et al.*, *J. Neurosci.* 18(22):9269-9281. (1998)).

30 As a family, SV2 proteins are widely distributed in the brain and in endocrine cells. The three isoforms overlap significantly in their distribution, and can be found co-expressed

in the same neuron, and even on the same synaptic vesicle. One isoform or another of the SV2 proteins seems to be present on all synaptic vesicles, and they are probably not limited to neurons that contain any specific neurotransmitters, although one study reports that cholinergic vesicles may not contain SV2 (Blumberg *et al.*, *J. Neurochem.* 58(3):801-810 (1992)). SV2 proteins are therefore one of the most common proteins of synaptic vesicles, and have been implicated in the control of calcium-mediated exocytosis of synaptic vesicles. SV2 proteins have also been shown to be expressed in endocrine cells and, along with the additional synaptic vesicle membrane integral proteins p38 and p65, has been demonstrated to be present in endocrine dense core granule membranes (Lowe *et al.*, *J. Cell. Biol.* 106(1):51-59 (1988)). SV2A, the most common SV2 isoform, is expressed ubiquitously throughout the brain, and is present as well in secretory granules of endocrine cells. SV2B, while broadly distributed in the brain, is undetected in several brain structures, including the dentate gyrus of the hippocampus, the globus pallidus, reticular nuclei of the thalamus, and the reticular part of the substantia nigra (Bajjalieh *et al.*, 1994). By contrast, SV2C has quite a limited distribution and is found primarily in the phylogenetically old regions such as the pallidum, the substantia nigra, the midbrain, the brainstem and the olfactory bulb. It is undetectable in the cerebral cortex and the hippocampus, and found at low levels in the cerebellar cortex (Janz and Sudhof, *Neuroscience* 94(4): 1279-1290. (1999)).

In addition to the SV2 protein, the synapse contains other unique regulatory proteins such as synapsin, synaptotagmin and CAPS, which may mediate vesicle fusion or budding. SV2A may be a  $\text{Ca}^{2+}$  regulatory protein essential for the formation of pre-fusion complexes called SNARE complexes (Xu *et al.* *Cell* 99(7):713-722 (1999)), which include the synaptic vesicle-associated VAMP/synaptobrevin and the plasma membrane proteins syntaxin and SNAP-25. Upon  $\text{Ca}^{2+}$  accumulation in the synapse the binding of synaptotagmin to SV2A is inhibited and the dimerization of two synaptotagmin  $\text{Ca}^{2+}$  binding domains is stimulated (Bajjalieh, *Curr. Opin. Neurobiol.* 9(3):321-328. (1999)). This dimerization may play a role in organizing the SNARE complex and promoting vesicle fusion, as at low  $\text{Ca}^{2+}$  concentrations, SV2A remains bound to synaptotagmin and fusion will not occur.

The affinity of SV2A for synaptotagmin is regulated by the phosphorylation of the amino terminus of SV2 (Pyle *et al.*, *J. Biol. Chem.* 275(22):17195-17200. (2000)). The possibility that SV2 proteins play a role in either  $\text{Ca}^{2+}$  transport, or regulation in the synaptic

vesicle has been supported by studies of SV2A and SV2B knockout animals (Janz *et al.*, Neuron 24:1003-1016. (1999)). An alternative hypothesis is that the SV2 proteins, while derived from transport proteins, now serve a different function in the vesicle, whether a structural role or a role in regulation of vesicle fusion or recycling and the exocytotic release 5 of their contents (Janz and Sudhof, Neuroscience 94(4): 1279-1290. (1999)).

There have been two reports of SV2 protein knockout mice: one that examines only SV2A knockouts (Crowder *et al.*, Proc. Nat. Acad. Sci. USA 96(26):15268-15273. (1999)) and the other which looks at both SV2A and SV2B knockout animals, as well as the SV2A/SV2B double knockout (Janz *et al.*, Neuron 24:1003-1016. (1999)).

10 Animals homozygous for SV2A gene disruption appear normal at birth, but fail to grow, experience severe seizures, and die within the first few weeks postnatal. SV2A homozygous knockout mice experience seizures that are longer lasting, stronger, and more debilitating than any other mouse strain (Janz *et al.*, Neuron 24:1003-1016. (1999)). Despite the appearance of postnatal seizures, all SV2A knockout animals have completely normal 15 gross brain morphology, including normal levels of the tested synaptic proteins. Furthermore, the hippocampal neuronal cultures from both SV2A and SV2A/SV2B double knockout mice formed synapses that were ultrastructurally normal, and had unchanged size, number and location of synaptic vesicles (Janz *et al.*, Neuron 24:1003-1016. (1999); Crowder *et al.*, Proc. Nat. Acad. Sci. USA 96(26):15268-15273. (1999)). Unlike the frequently 20 observed seizures caused by structural and developmental abnormalities easily detected in many other type of knockouts, the SV2A knockout mice show a strong seizure phenotype with no associated macro or micro scale abnormalities of the brain or synapse. As another marker of brain function, studies of synaptic transmission in primary neuronal cultures from SV2A, SV2B, and SV2A/SV2B knockout mice indicate that the sizes and frequencies of 25 sIPSCs and of spontaneous excitatory postsynaptic currents (sEPSCs), are normal. Electrical stimulation induced robust EPSCs and IPSCs in the cultured neurons from all genotypes.

In contrast to SV2A, SV2B knockout mice reveal no overt pathology (Janz *et al.*, 1999). It is suggested that one possible reason for this lack of consequence of loss of SV2B is that can be functionally replaced by SV2A, which appears to be co-expressed everywhere 30 SV2B is normally expressed.

While the function of SV2A and other family members still remains unknown, one

hypothesis is that this transporter homologue is a functional transporter for some common synaptic vesicle molecule. More specifically, there is evidence linking SV2A to the regulation of calcium-mediated vesicle exocytosis, and as a result, it is thought that it may be a  $\text{Ca}^{2+}$  transporter. SV2A and other family members may also have roles in the function of 5 synaptic vesicles. Such roles may include modulating aspects of their formation, loading with neurotransmitter, fusion with the plasma membrane, re-cycling, and interactions with other proteins and cellular compartments and organelles. For instance it has been shown that SV2 proteins can interact with the synaptic vesicle protein synaptotagmin and the extracellular matrix protein laminin-1 (Carlson, Perspect. Dev. Neurobiol. 3(4):373-386 10 (1996)). The SV2 proteins may play important roles in regulating cytoplasmic or organellar calcium levels at the presynaptic terminal, and may also interact with N-type calcium channels on the plasma membrane, either directly or indirectly.

## SUMMARY OF THE INVENTION

15 The present inventors have discovered that SV2A is the binding site for the anti-seizure drug LEV and its analogs. The high degree of correlation between relative binding affinities of a series of levetiracetam analogues and their anti-convulsant potencies in certain animal models of epilepsy provides strong evidence that binding of these analogues to SV2 proteins modifies their function to provide anticonvulsant effects.

20 In a preferred embodiment, the invention includes a method of treating a neurological disorder associated with synaptic vesicle function, endocrinopathy or hormonal diseases, comprising administering a compound or agent that modulates a function or activity of an SV2 protein.

25 In another preferred embodiment, the invention includes a method of discovering or modeling an interaction between an SV2 protein and a compound or agent selected from the group consisting of: levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site. The method comprises contacting the SV2 protein with the compound or agent measuring and analyzing the interaction of the SV2 protein with the 30 compound or agent.

In another preferred embodiment, the invention includes a method of identifying a

levetiracetam binding site within an SV2 protein. The method comprises contacting a SV2 protein or fragment thereof with a compound or agent selected from the group consisting of levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the

5 levetiracetam binding site and determining the binding of the compound or agent with the SV2 protein or fragment thereof.

In another preferred embodiment, the invention includes a method of assaying the interaction between SV2 protein and a second protein. The method comprises expressing SV2 protein and the protein of interest in a cell. The method further comprises exposing the 10 cell to a compound or agent which binds to the levetiracetam binding site and determining the interaction between the SV2 protein and the protein of interest.

15 In another preferred embodiment, the invention includes a method of identifying a compound or agent that modulates a neurological disorder associated with synaptic function, endocrinopathy or hormonal disease. The method comprises exposing a SV2 protein to the compound or agent and determining whether the compound or agent modulates an activity of the SV2 protein.

20 In another preferred embodiment, the invention includes a method of identifying a cellular response to a compound or agent selected from the group consisting of levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site. The method comprises exposing cells expressing an SV2 protein to the compound or agent and analyzing a change in the expression of a nucleic acid or protein in the exposed cell. The nucleic acid could be RNA, and the expression of the RNA may be analyzed by hybridization, such as hybridization on a microarray.

25 In another preferred embodiment, the invention includes an isolated nucleic acid molecule comprising the nucleic acid sequence of SEQ ID NO: 5 or the complement thereof.

30 In another preferred embodiment, the invention includes a method of identifying a binding partner for a SV2 protein. The method comprises exposing a SV2 protein or fragment to a potential binding partner and incubating the protein or fragment and potential binding partner with (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide. The method further comprises determining if the binding of (2S)-2-[4-(3-azidophenyl)-2-

oxopyrrolidin-1-yl]butanamide to the protein is inhibited by the potential binding partner, thereby identifying binding partner for the protein.

In still another preferred embodiment, the invention includes a method of identifying an agent useful for the treatment of a neurological or endocrinological disorder. The method 5 comprises exposing a SV2 protein or fragment to the agent and levetiracetam or an analog or derivative thereof. The method further comprises determining if the binding of levetiracetam or an analog or derivative thereof to the protein is modulated by the agent, thereby identifying an agent useful for the treatment of a neurological or endocrinological disorder.

In yet another preferred embodiment, the invention includes a method of identifying 10 an agent useful for the treatment of a neurological or endocrinological disorder. The method comprises exposing a SV2 protein or fragment to the agent and incubating the protein or fragment and agent with (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide. The method further comprises determining if the binding of (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide to the protein is inhibited by the agent, thereby identifying 15 binding partners for the protein.

In another preferred embodiment, the invention includes a method of discovering or 20 modeling an interaction between an SV2 protein, or fragment or derivative thereof, and a compound or agent selected from the group consisting of: levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site. The method comprises creating a 3-dimensional model of the SV2 protein, or fragments thereof, via either biochemical, biophysical, purely computational techniques, or some combination of these and creating 25 3-dimensional model of one or a collection of potential ligands that might potentially bind the SV2 protein.

In another preferred embodiment, the invention includes a method of discovering or 30 modeling an interaction between an SV2 protein and a compound or agent selected from the group consisting of: levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site. The method comprises determining a biochemical, pharmacological, organismal, cellular or molecular effect of a potential CNS active molecule in a genetically wild-type animal or in molecules, cells or tissues derived from such animals

and comparing the measured effect of that compound in an equivalent study in a system with an SV2 protein knocked out or knocked down.

The present invention also provides biotinylated ligands as tools to screen chemical libraries, localize SV2 proteins in tissues, and characterize purified SV2 proteins. SV2 5 proteins of the present invention includes SV2A, SV2B, and SV2C. Ligands of SV2/LBS, specifically SV2A/LBS, and their derivatives may be biotinylated for screening naturally occurring brain membranes, such as animal, mammalian, or human brain membranes, or for screening cell lines expressing SV2 proteins. The present invention also provides photoactivable biotinylated ligands of SV2/LBS. These screening assays enable the 10 identification of new drugs or compounds that interact with SV2.

Further, the present invention provides a method of purifying a membrane associated protein comprising solubilizing the protein from a tissue to form a solubilized complex and isolating the solubilized complex in a functional form. The solubilized protein or complex may be affinity purified using antibodies that bind to the protein. Examples of membrane 15 associated proteins that may be purified by this method include the family of SV2 proteins such as SV2A, SV2B, and SV2C. The detergents that may be used in the present method includes n-dodecyl- $\beta$ -maltoside and its analogs or derivatives such as n-octyl, n-nonyl, n-decyl, n-undecyl- $\beta$ -D-maltoside.

The biotinylated ligands also can be used as tools to assess the conformation state of 20 SV2 proteins after solubilization, immunoaffinity purification, and chromatography.

In one embodiment, the SV2 protein may be a fusion protein comprising at least one SV2 protein or fragment thereof and fusion partner. The fusion partner may be a fusion tag, such as a poly-histidine tag or a glutathione-S-transferase tag. The fusion partner may be attached to the N-terminus or the C-terminus of the SV2 protein.

25 In another embodiment, the protein, such as the SV2 protein, may lack at least one glycosylation site. In some instances, site-directed mutagenesis may be performed to remove one or more glycosylation site in the SV2 protein.

The SV2 protein or fragment may be purified from natural sources such as mammalian 30 membranes, for example, rat brain membrane. Alternatively, the SV2 protein or fragment is expressed on a transformed host cell. Additionally, the SV2 protein or fragment is immobilized.

In one aspect, the ligand could be directly or indirectly labeled. The label could be a radiolabel, such as  $^3\text{H}$ , a fluorescent label, or an enzyme.

### BRIEF DESCRIPTION OF THE DRAWINGS

5 Figure 1 depicts the reversible binding of the LEV analog ucb 30889 to LBS in rat brain cortex.

Figure 2 depicts the saturation binding curves of ucb 30889.

Figure 3 shows that specific binding could not be detected in the peripheral tissues.

10 Figure 4 depicts competition binding curves showing that ucb 30889 binds to LBS with about 10 fold higher affinity than LEV.

Figure 5 depicts  $\text{pIC}_{50}$  values for ucb 30889 versus levetiracetam.

Figure 6 depicts the concentration dependent inhibition of  $[^3\text{H}]$ ucb 30889 binding by unlabeled levetiracetam in autoradiography of rat brain.

15 Figure 7 depicts autoradiography of  $[^3\text{H}]$ ucb 30889 binding to coronal sections of rat brain.

Figure 8 depicts the subcellular distribution of  $[^3\text{H}]$ ucb 30889 binding within rat brain.

Figure 9 depicts the subfractionation of the synaptosomal fraction by centrifugation in sucrose gradient.

20 Figure 10 depicts the photolabelling of the LBS by  $[^3\text{H}]$ ucb 30889 and irreversibility of the complex.

Figure 11 depicts gel electrophoresis of membrane proteins labeled by  $[^3\text{H}]$ ucb 30889.

25 Figure 12 (A and B) depicts immunostained lysates of the COS-7 cells transfected with SV2A, crude rat brain membranes, and several different PC12 lysates with different levels of LBS.

Figure 13 depicts specific binding of  $[^3\text{H}]$ ucb 30889 to COS-7 transfected with SV2A-12.2, transfected with control  $\beta$ -gal expressing vector, or cells that have not been transfected.

30 Figure 14 depicts an  $\text{IC}_{50}$  plot comparing three different ligands binding to SV2A in the presence of 3H-30889.

Figure 15 depicts the structure of (A) levetiracetam and (B) ucb 30889.

Figure 16 (A and B) depicts binding of [<sup>3</sup>H]ucb 30889 to brain membranes. A. Binding of [<sup>3</sup>H]ucb 30889 to brain membranes from SV2A, SV2B, and SV2A/SV2B knockout mice. [<sup>3</sup>H]ucb 30889 alone (□) [<sup>3</sup>H]ucb 30889 plus 1mM LEV (■). Error bars are the SD of experiments performed with 5 wildtype brains and 4 KO brains. Each 5 experiment was performed in triplicate. B. Western blot of brain membranes from wild type and homozygous knockout mice probed with an anti-SV2 monoclonal antibody (cross-reactive to all isoforms, SV2A, SV2B and SV2C). LANES 1: wt; 2: SV2A ko; 3 SV2B ko; 4: SV2A/B double ko.

Figure 17 (A and B) depicts binding of [<sup>3</sup>H]ucb 30889 to COS-7 cells expressing 10 hSV2A. A. Binding of [<sup>3</sup>H]ucb 30889 to hSV2A transiently expressed in COS-7 cells. [<sup>3</sup>H]ucb 30889 is tested for binding to either untransfected COS-7 cells, or COS-7 cells transiently expressing either □-gal or hSV2A. [<sup>3</sup>H]ucb 30889 alone (□) [<sup>3</sup>H]ucb 30889 plus 1mM LEV (■). B. IC<sub>50</sub> curves of LEV, ucb L060, ucb 30889 against hSV2A 15 transiently expressed in COS-7, in the presence of [<sup>3</sup>H]ucb 30889. LEV (Δ) ucb 30889 (■) ucb L060 (●). Error bars are SEM, n=3.

Figure 18 (A and B) depicts binding of [<sup>3</sup>H]ucb 30889 in the presence of competing 20 drugs. A. Correlation of binding of a series of LEV compounds to mouse brain and to hSV2A, pIC<sub>50</sub>s measured against [<sup>3</sup>H]ucb 30889. The pIC<sub>50</sub> values are the mean of two independent experiments, where each determination lies within 0.2 log units of the mean. B. Correlation of binding of a series of LEV family compounds to hSV2A assayed in transiently 25 transfected COS-7 cells, pIC<sub>50</sub>s measured against [<sup>3</sup>H]ucb 30889, and of anti-seizure potencies in the mouse audiogenic model.

Figure 19 depicts the structure of ucb-101282-1. This ligand is a biotinylated derivative of ucb 30889.

Figure 20 depicts that the pKi of ucb-101282-1 is 6.3 (n=2) in rat brain membranes which is equivalent to the affinity reported for LEV.

Figure 21 (A, B, and C) depicts preparation of soluble SV2A and quantitation of by binding assay. A. Detection by western blot using anti-SV2A antibodies of soluble SV2A in the supernatant of solubilized rat brain membranes. B. Analysis of the ability of 30 levetiracetam and ucb 30889 to specifically bind to soluble SV2A. C. Scatchard analysis indicates that the K<sub>D</sub> for the binding of [<sup>3</sup>H] ucb 30889 to SV2A in native rat brain membrane

is 30 nM, while that for the soluble protein is 82 nM.

Figure 22 depicts identification of SV2A partners. Western blot analysis show synaptotagmin associated to soluble SV2A in the immunopurified fractions of the supernatants from solubilized rat brain membranes. The isoform SV2B was not detected.

5

## DETAILED DESCRIPTION

### I. Synaptic Vesicle Protein 2 (SV2) Family of Proteins

Any SV2 protein that binds LEV or a derivative or analog thereof may be used in the assays herein described.

10 As used herein, SV2 proteins include isolated proteins, allelic variants of the proteins, and conservative amino acid substitutions of the proteins. As used herein, the "protein" or "polypeptide" refers, in part, to SV2A, a protein encoded by the nucleic acid sequence of SEQ ID NO: 1 or that has the human amino acid sequence depicted in SEQ ID NO: 2 or fragments thereof; to SV2B, which includes the human protein encoded by the nucleic acid 15 sequence of SEQ ID NO: 3 or the amino acid sequence depicted in SEQ ID NO: 4 or fragments thereof; to SV2C, which includes the human protein encoded by the nucleic acid sequence of SEQ ID NO: 5 or the amino acid sequence depicted in SEQ ID NO: 6 or fragments thereof; and to SVOP, which includes the human protein encoded by the nucleic acid sequence of SEQ ID NO: 7 or the amino acid sequence depicted in SEQ ID NO: 8 or 20 fragments thereof. The terms also refer to naturally occurring allelic variants and proteins that have a slightly different amino acid sequence than that specifically recited above. Allelic variants, though possessing a slightly different amino acid sequence than those recited above, will still have the same or similar biological functions associated with these proteins.

As used herein, the family of SV2 proteins related to the human amino acid sequence 25 of SEQ ID NO: 2, 4, 6 or 8 refers in part, to proteins that have been isolated from organisms in addition to humans. For example, rat homologues of SV2A nucleic acid (SEQ ID NO: 9) and protein (SEQ ID NO: 10), SV2B nucleic acid (SEQ ID NO: 11) and protein (SEQ ID NO: 12), SV2C nucleic acid (SEQ ID NO: 13) and protein (SEQ ID NO: 14) and SVOP nucleic acid (SEQ ID NO: 15) and protein (SEQ ID NO: 16) have been identified and are 30 included herein. The methods used to identify and isolate other members of the family of proteins related to these proteins are described below.

The SV2 proteins used in the present invention are preferably in isolated form in part of a cellular or vesicle membrane fragment, expressed in a transformed host cell, or naturally expressed in a given cell or tissue type. As used herein, a protein is said to be isolated when physical, mechanical or chemical methods are employed to remove the protein from cellular constituents that are normally associated with the protein. A skilled artisan can readily employ standard purification methods to obtain an isolated protein.

The SV2 proteins that may be used in the methods of the invention further include insertion, deletion, conservative amino acid substitution or splice variants of SEQ ID NO: 2, 4, 6, 8, 10, 12, 14 or 16. As used herein, a "conservative" variant refers to alterations in the amino acid sequence that do not adversely affect the biological functions of the protein. A substitution, insertion or deletion is said to adversely affect the protein when the altered sequence prevents or disrupts a biological function associated with the protein. For example, the overall charge, structure or hydrophobic/hydrophilic properties of the protein can be altered without adversely affecting a biological activity. Accordingly, the amino acid sequence can be altered, for example to render the peptide more hydrophobic or hydrophilic, without adversely affecting the biological activities of the protein. As used herein, a "deletion" is defined as a change in either nucleotide or amino acid sequence in which one or more nucleotides or amino acid residues, respectively, are absent; an "insertion" or "addition" is that change in a nucleotide or amino acid sequence which has resulted in the addition of one or more nucleotides or amino acid residues, respectively, as compared to the naturally occurring SV2 and a "substitution" results from the replacement of one or more nucleotides or amino acids by different nucleotides or amino acids, respectively.

SV2 proteins of the present invention further include fusion proteins, wherein a SV2 protein, or fragment thereof, is N- or C- terminally fused to another SV2 protein or fragment thereof, which may be the same as or different from the first SV2 protein or fragment thereof, and/or to a heterologous peptide fusion partner. The heterologous peptide may be a polypeptide sequence useful for the expression, purification, solubility, identification, antigenicity, or extension of the stability of the SV2 protein or fragment thereof. Heterologous fusion partners useful in the present invention include, but are not limited to, glutathione-S-transferase (GST), poly-histidine tags, green fluorescent protein (GFP), albumin, and ovalbumin or fragments thereof.

Ordinarily, the allelic variants, the conservative substitution variants, and the members of the SV2 protein family, will have an amino acid sequence having at least about 35%, 40%, 50%, 60%, 65%, 70% or 75% amino acid sequence identity with the full length sequence set forth in SEQ ID NO: 2, 4, 6, 8, 10, 12, 14 or 16 more preferably at least about 5 80%, even more preferably at least about 90%, and most preferably at least about 95%, 97% or 99% sequence identity. Identity or homology with respect to such sequences is defined herein as the percentage of amino acid residues in the candidate sequence that are identical with the known peptides, after aligning the sequences and introducing gaps, if necessary, to achieve the maximum percent homology, and not considering any conservative substitutions 10 as part of the sequence identity (see section B for the relevant parameters). Fusion proteins, or N-terminal, C-terminal or internal extensions, deletions, or insertions into the peptide sequence shall not be construed as affecting homology.

Contemplated variants further include those containing predetermined mutations by, e.g., homologous recombination, site-directed or PCR mutagenesis, and the corresponding 15 proteins of other animal species, including but not limited to rabbit, mouse, rat, porcine, bovine, ovine, equine and non-human primate species, and the alleles or other naturally occurring variants of the family of proteins; and derivatives wherein the protein has been covalently modified by substitution, chemical, enzymatic, or other appropriate means with a moiety other than a naturally occurring amino acid (for example a detectable moiety such as 20 an enzyme or radioisotope).

Fragments of the SV2 proteins may also be used in the methods of the invention. In particular, fragments comprising the LEV binding site may be used. Such fragments may have at least about 6 or 10, 15 or 20, or 25 or 30 amino acid residues, about 35 or 40 amino acid residues, about 45 or 50 amino acid residues, about 55 or 60, about 65 or 70 amino acid 25 residues or at least about 75 or more amino acid residues

The methods of the present invention may also utilize nucleic acid molecules that encode members of the SV2 protein family, including, but not limited to, both the rat and human proteins known as SV2A, SV2B, SV2C and the related synaptic vesicle protein SVOP, such as those consisting of or comprising SEQ ID NO: 2, 4, 6, 8, 10, 12, 14 or 16 and 30 the related proteins herein described, preferably in isolated form. Vectors, plasmids and transformed host cells may also be used to produce an SV2 protein. As used herein, "nucleic

acid" is defined as RNA or DNA or related molecules that encodes a protein or peptide as defined above, is complementary to a nucleic acid sequence encoding such peptides, hybridizes to such a nucleic acid and remains stably bound to it under appropriate stringency conditions, or encodes a polypeptide sharing at least about 35%, 40%, 50%, 60%, 65%, 70% 5 or 75% sequence identity, preferably at least about 80%, more preferably at least about 85%, and even more preferably at least about 90%, 95%, 97% or 99% or more identity with the full-length peptide sequence of SEQ ID NO: 2, 4, 6, 8, or 10. The "nucleic acid molecules" useful in the invention further include nucleic acid molecules that share at least about 70% or 10 75% sequence identity, preferably at least about 80%, more preferably at least about 85%, and even more preferably at least about 90% and most preferably 95%, 97%, 99% or more identity with the nucleotide sequence of SEQ ID NO: 1, 3, 5, 7, or 9. Nucleic acids of the present invention also include those which encode fusion proteins comprising a SV2 protein either N- or C- terminally fused to a heterologous protein sequence or to another SV2 protein sequence.

15 Homology or identity at the nucleotide or amino acid sequence level is determined by **BLAST** (Basic Local Alignment Search Tool) analysis using the algorithm employed by the programs **blastp**, **blastn**, **blastx**, **tblastn** and **tblastx** (Altschul, *et al.*, Nucleic Acids Res. 25: 3389-3402 (1997); Karlin *et al.*, Proc. Natl. Acad. Sci. USA 87:2264-2268 (1990)) which are tailored for sequence similarity searching. The approach used by the **BLAST** program is to 20 first consider similar segments, with and without gaps, between a query sequence and a database sequence, then to evaluate the statistical significance of all matches that are identified and finally to summarize only those matches which satisfy a pre-selected threshold of significance. For a discussion of basic issues in similarity searching of sequence databases, see Altschul *et al.*, (Nature Genetics 6, 119-129 (1994)). The search parameters for 25 **histogram**, **descriptions**, **alignments**, **expect** (*i.e.*, the statistical significance threshold for reporting matches against database sequences), **cutoff**, **matrix** and **filter** (low complexity) are at the default settings. The default scoring matrix used by **blastp**, **blastx**, **tblastn**, and **tblastx** is the **BLOSUM62** matrix (Henikoff *et al.*, Proc. Natl. Acad. Sci. USA 89:10915-10919 (1992)), recommended for query sequences over 85 in length (nucleotide bases or 30 amino acids).

For **blastn**, the scoring matrix is set by the ratios of **M** (*i.e.*, the reward score for a pair

of matching-residues) to N (*i.e.*, the penalty score for mismatching residues), wherein the default values for M and N are +5 and -4, respectively. Four **blastn** parameters were adjusted as follows: Q=10 (gap creation penalty); R=10 (gap extension penalty); *wink*=1 (generates word hits at every *wink*<sup>th</sup> position along the query); and *gapw*=16 (sets the window width within which gapped alignments are generated). The equivalent **Blastp** parameter settings were Q=9; R=2; *wink*=1; and *gapw*=32. A **Gap** comparison between sequences, available in the Accelrys' Wisconsin Package version 10.2, uses DNA parameters *GAP*=50 (gap creation penalty) and *LEN*=3 (gap extension penalty) and the equivalent settings in protein comparisons are *GAP*=8 and *LEN*=2.

“Stringent conditions” include those that (1) employ low ionic strength and high temperature for washing, for example, 0.015 M NaCl/0.0015 M sodium citrate/0.1% SDS at 50°C, or (2) employ during hybridization a denaturing agent such as formamide, for example, 50% (vol/vol) formamide with 0.1% bovine serum albumin/0.1% Ficoll/0.1% polyvinylpyrrolidone/50 mM sodium phosphate buffer at pH 6.5 with 750 mM NaCl, 75 mM sodium citrate at 42°C. Another example is hybridization in 50% formamide, 5× SSC (0.75 M NaCl, 0.075 M sodium citrate), 50 mM sodium phosphate (pH 6.8), 0.1% sodium pyrophosphate, 5× Denhardt's solution, sonicated salmon sperm DNA (50 µg/ml), 0.1% SDS, and 10% dextran sulfate at 42°C, with washes at 42°C in 0.2× SSC and 0.1% SDS. A skilled artisan can readily determine and vary the stringency conditions appropriately to obtain a clear and detectable hybridization signal. Preferred molecules are those that hybridize under the above conditions to the complement of SEQ ID NO: 1, 3, 5, 7, 9, 11, 13 or 15 and which encode a functional protein. Even more preferred hybridizing molecules are those that hybridize under the above conditions to the complement strand of the open reading frame of SEQ ID NO: 1, 3, 5, 7, 9, 11, 13 or 15.

As used herein, a nucleic acid molecule is said to be “isolated” when the nucleic acid molecule is substantially separated from contaminant nucleic acid molecules encoding other polypeptides.

#### **A. SV2A and the Levetiracetam Binding Site (LBS)**

The invention includes the characterization and use of the LBS located on the SV2A protein.

As described above, "SV2A" includes the human protein as described in SEQ ID NO: 2, the human protein encoded by SEQ ID NO: 1, species homologues of human SV2A, variants of SEQ ID NO: 2 as herein described, and fragments of SV2A comprising the LBS.

5      **II. Levetiracetam and Analogs**

The methods of the invention include the use of LEV and LEV analogs or derivatives thereof in assays to identify new pharmacological agents. In a preferred embodiment, the methods of the present invention identify compounds or agents that compete with LEV and LEV analogs or derivatives thereof for binding to the LBS of SV2. As used herein, the terms 10 "compete" and "competitive binding" refer to agents or compounds which occupy the same binding site on the LBS as LEV or analogs or derivatives thereof; displace, or are displaced by, LEV or analogs or derivatives thereof in binding to the LBS; or inhibit, or are inhibited by, LEV or analogs or derivatives thereof in binding to the LBS. In another preferred embodiment, the invention includes the identification of compounds or agents that modulate 15 the activity of SV2A. In another preferred embodiment the methods of the present invention identify compounds or agents which have less, about the same, or greater affinity for the LBS than LEV. In yet another preferred embodiment the methods of the present invention identify compounds or agents which have less, about the same, or greater affinity for the LBS than ucB 30889. In still another preferred embodiment the methods of the present invention 20 identify compounds or agents which in an effective amount modulate the activity of SV2A for a longer period of time than an effective amount of LEV. In even another preferred embodiment the methods of the present invention identify compounds or agents which in an effective amount modulate the activity of SV2A for a shorter period of time than an effective amount of LEV.

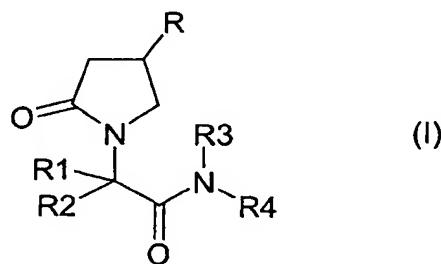

25      As used herein, "levetiracetam" (Figure 15A; LEV), refers to the International Non-proprietary name of the compound (S)- $\alpha$ -ethyl-2-oxo-1-pyrrolidine acetamide as disclosed in European Patent No. 0 162 036 B1, herein incorporated by reference in its entirety. LEV is a levorotatory compound which is a protective agent for the treatment and prevention of hypoxic and ischemic type aggressions of the central nervous system. This compound is also 30 effective in the treatment of epilepsy. Racemic  $\alpha$ -ethyl-2-oxo-1-pyrrolidine acetamide and

analog thereof are known from British Patent No. 1 309 692. US Patent No. 3,459,738 discloses derivatives of 2-oxo-1-pyrrolidine acetamide.

As used herein, the term "LEV analogs or derivatives thereof" includes optionally substituted N-alkylated 2-oxo-pyrrolidine derivatives. Preferably, those compounds are alkyl amides derivatives substituted on the positions 4 and/or 5 of the pyrrolidone ring. Examples of optionally substituted N-alkylated 2-oxo-pyrrolidine derivatives include, but are not limited to, compounds such as those disclosed in international patent application PCT/EP01/01992 such as (2S)-2-[(4S)-4-(2,2-difluorovinyl)-2-oxopyrrolidinyl]butanamide, (2S)-2-[(4R)-2-oxo-4-propylpyrrolidinyl]butanamide, (2S)-2-[(4S)-2-oxo-4-propylpyrrolidinyl]butanamide, and (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide.

As used herein, the term "LEV analogs or derivatives thereof" further include optionally substituted N-alkylated 2-oxo-piperidinyl derivatives. Preferably, those compounds are alkyl amides derivatives substituted on the position 4 and/or 5 and/or 6 of the 2-oxo-piperidinyl ring. Examples of optionally substituted N-alkylated 2-oxo-pyrrolidine derivatives include, but are not limited to, compounds such as those disclosed in international patent application PCT/EP02/05503 such as (2S)-2-[5-(iodomethyl)-2-oxo-1-piperidinyl]butanamide, (2S)-2-[5-(azidomethyl)-2-oxo-1-piperidinyl]butanamide, 2-(2-oxo-5-phenyl-1-piperidinyl]butanamide, (2S)-2-[4-(iodomethyl)-2-oxo-1-piperidinyl]butanamide, and (2S)-2-[4-(2-fluoro-2-methylpropyl)-2-oxo-1-pyrrolidinyl]butanamide.

As used herein, the term "LEV analogs or derivatives thereof" includes any acetam compound of formula I, in racemic or isomeric form, or a pharmaceutically acceptable salts thereof,

25 wherein

- R represents hydrogen or hydroxy;
- R<sup>1</sup> and R<sup>2</sup> represent independently hydrogen or an alkyl group of 1-4 carbon atoms; and
- R<sup>3</sup> and R<sup>4</sup> represent independently hydrogen, an alkyl group of 1-4 carbon atoms or -(CH<sub>2</sub>)<sub>n</sub> - NR<sup>5</sup>R<sup>6</sup> wherein n is 1, 2 or 3 and R<sup>5</sup> and R<sup>6</sup> represent independently hydrogen or an alkyl group of 1-4 carbon atoms.

5 An example of such an acetam compound includes, but is not limited to, a compound of formula I wherein R, R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup> and R<sup>4</sup> are hydrogen, 2-oxo-pyrrolidineacetamide, known by the generic name piracetam as described in UK Patents Nos. 1,039,113 and  
10 1,309,692.

As used herein, the term "LEV analogs or derivatives thereof" also include optionally substituted N-alkylated 2-oxo-azepanyl derivatives. Preferably, those compounds are alkyl amides derivatives substituted on the positions 4 and/or 5 and/or 6 and/or 7 of the 2-oxo-azepanyl ring. Examples of optionally substituted N-alkylated 2-oxo-azepanyl derivatives  
15 include, but are not limited to, compounds such as those disclosed in international patent application PCT/EP02/05503 such as 2-[5-(iodomethyl)-2-oxo-1-azepanyl]butanamide.

In another embodiment the present invention includes compounds or agents which are derivatives or analogs of piracetam which bind to the LBS. Such compounds would also include molecules such as aniracetam and nefiracetam. In a preferred embodiment, the  
20 derivatives or analogs of piracetam are those which modulate the activity of SV2A or other SV2 family members.

### III. Assay Formats

Assays of the present invention include methods of identifying agents or compounds  
25 which are useful for the treatment of neurological disorders, such as seizures, epilepsy, Parkinson's disease, Parkinson's dyskinesias, migraine, Alzheimer's disease, neuropathic pain, essential tremor, cognitive disorders, movement disorders, endocrinopathy and adrenal-medulla-related disease, such as hypoglycemia and circulation shock. Assays of the present invention also include methods of identifying agents or compounds which have cognitive  
30 enhancing effects, such as for example might be measured in animal models of cognition. In particular, the assays of the present invention include methods of identifying agents or

compounds that compete with LEV or analogs or derivatives thereof for binding to the LBS of SV2A, displace, or are displaced by, LEV or analogs or derivatives thereof in binding to the LBS; or inhibit, or are inhibited by, LEV or analogs or derivatives thereof in binding to the LBS.

5 LEV, ucb 30889 (Figure 15B)and other derivatives or analogs of LEV as described above are useful in the methods of the invention as binders in assays to screen for new compounds or agents that bind to the LBS of SV2A. In such assay embodiments, LEV, ucb 30889 and derivatives or analogs can be used without modification or can be modified in a variety of ways; for example, by labeling, such as covalently or non-covalently joining a  
10 moiety which directly or indirectly provides a detectable signal. In any of these assays, the materials can be labeled either directly or indirectly. Possibilities for direct labeling include label groups such as: radiolabels including, but not limited to, [<sup>3</sup>H], [<sup>14</sup>C], [<sup>32</sup>P], [<sup>35</sup>S] or [<sup>125</sup>I], enzymes such as peroxidase and alkaline phosphatase, and fluorescent labels capable of monitoring the change in fluorescence intensity, wavelength shift, or fluorescence  
15 polarization, including, but not limited to, fluorescein or rhodamine. In addition, FRET techniques could be used to analyze interactions between ligands and the LBS of SV2A. Possibilities for indirect labeling include biotinylation of one constituent followed by binding to avidin coupled to one of the above label groups or the use of anti-ligand antibodies. The compounds may also include spacers or linkers in cases where the compounds are to be  
20 attached to a solid support.

To identify agents or compounds which compete or interact with LEV and ucb 30889 and derivatives for binding to the LBS of SV2A, intact cells, cellular or membrane fragments containing SV2A or the entire SV2A protein or a fragment comprising the LBS of the SV2A protein can be used. The agent or compound may be incubated with the cells, membranes,  
25 SV2 protein or fragment prior to, at the same time as, or after incubation with LEV or an analog or derivative thereof. Assays of the present invention can measure any property or function known for SV2 proteins, synaptic vesicles, neural transmission and/or endocrine cell function, as well as presynaptic accumulation of divalent cations, including Ca<sup>2+</sup>. Examples of properties or functions of an SV2 protein which may be measured as an assay endpoint  
30 include, but are not limited to, phosphorylation state, binding of divalent cations, including Ca<sup>2+</sup>; membrane transport; transport of divalent cations (including Ca<sup>2+</sup>) into and/or out of

synaptic vesicles; transport of neurotransmitters (including, but not limited to amines, acetylcholine, excitatory neurotransmitters, GABA, serotonin, and glycine) into and/or out of synaptic vesicles; interaction with other proteins (including, but not limited to laminins and synaptotagmin); conformational changes, as measured by sensitivity to proteolysis or other changes in biochemical or biophysical properties; divalent cation channel formation; formation or dissociation of protein complexes; synaptic vesicle function; fusion; exocytosis; and synaptic vesicle recycling.

Assays of the invention may be modified or prepared in any available format, including high-throughput assays that monitor the binding of LEV or the binding of derivatives or analogs thereof to SV2A or to the LBS of the SV2A protein. In many drug screening programs which test libraries of compounds, high throughput assays are desirable in order to maximize the number of compounds surveyed in a given period of time. Such screening assays may use intact cells, cellular or membrane fragments containing SV2A as well as cell-free or membrane-free systems, such as may be derived with purified or semi-purified proteins. The advantage of the assay with membrane fragment containing SV2A or purified SV2A proteins and peptides is that the effects of cellular toxicity and/or bioavailability of the test compound can be generally ignored, the assay instead being focused primarily on the effect of the drug on the molecular target as may be manifest in an inhibition of, for instance, binding between two molecules.

In one embodiment of a competitive screening assay, the assay can be formulated to detect the ability of a test agent or compound to inhibit binding of ucb 30889 to SV2A or a fragment of SV2A comprising the LBS or of LEV, or derivatives or analogs thereof, to SV2A or a fragment of SV2A comprising the LBS. In another embodiment of a competitive screening assay, the assay can be formulated to detect the ability of ucb 30889 or of LEV, or derivatives or analogs thereof, to inhibit binding of a test agent or compound to SV2A or a fragment of SV2A comprising the LBS. The inhibition of complex formation may be detected by a variety of techniques. For instance, modulation of the formation of complexes can be quantitated using, for example, detectably labeled ucb 30889, LEV, or derivatives or analogs of LEV. The inhibition of complex formation may be detected by using a detectably labeled version of the agent or compound being assayed for competitive binding to the LBS of SV2A. Alternatively, the binding between the SV2A protein and a ligand may be detected

with no need of a labeled probe. For instance surface plasmon resonance, nuclear magnetic resonance or mass spectrometry are the instruments of choice for such binding assays.

Another method is to measure changes in the sensitivity of SV2 proteins to proteases induced by binding of a ligand.

5 In certain instances, it will be desirable to immobilize one of the LBS (SV2A or a fragment of SV2A comprising the LBS) or the ligand (LEV, ucb 30889 or the test agent or compound) to facilitate separation of complexes from uncomplexed forms, as well as to accommodate automation of the assay. Binding of a ligand to the LBS, for instance binding of a candidate agent or compound to SV2A, in the presence and absence of LEV or ucb

10 30889, can be accomplished in any vessel suitable for containing the reactants. Examples include microtiter plates, test tubes, and micro-centrifuge tubes. In one embodiment, a fusion protein can be provided which adds a domain that allows the LBS to be bound to a matrix. For example, glutathione-S-transferase(GST) fusion proteins can be adsorbed onto glutathione sepharose beads (Sigma Chemical, St. Louis, Mo.) or glutathione derivatized

15 microtiter plates, which are then combined with the labeled LEV, ucb 30889, or derivatives or analogs of LEV and the unlabeled test agent or compound; or alternatively, with the unlabeled LEV, ucb 30889, or derivatives or analogs of LEV and the labeled test agent or compound. The mixture is then incubated under conditions conducive to complex formation. Following incubation, the beads are washed to remove any unbound reactants, and the matrix

20 immobilized label determined directly, or in the supernatant after the LBS/ligand complexes are subsequently dissociated. When amenable, the complexes can be dissociated from the matrix, separated by SDS-PAGE, and the level of ligand found in the bead fraction quantitated from the gel using standard electrophoretic techniques.

Other techniques for immobilizing proteins on matrices are also available for use in  
25 the subject assay. For instance, the LBS can be immobilized utilizing conjugation of biotin and streptavidin. Biotinylated molecules can be prepared from biotin-NHS (N-hydroxy-succinimide) using techniques well known in the art (e.g., biotinylation kit, Pierce Chemicals, Rockford, Ill.), and immobilized in the wells of streptavidin-coated 96 well plates (Pierce Chemical). Alternatively, antibodies reactive with the LBS but which do not interfere with  
30 ligand binding can be derivatized to the wells of the plate, and LBS binding trapped in the wells by antibody conjugation. As above, preparations of a ligand and a test compound are

incubated in the protein-presenting wells of the plate, and the amount of protein/ligand complex trapped in the well can be quantitated. Exemplary methods for detecting such complexes, in addition to those described above, include immunodetection of complexes using antibodies reactive with the ligand, or which are reactive with the protein and compete 5 for binding with the ligand.

In another embodiment of the invention, competitive binding assays can be carried out using cellular extracts of cells or tissues that comprise the LBS to identify SV2 binding partners. As used herein, a cellular extract refers to a preparation or fraction that is made from a lysed or disrupted cell. The preferred source of cellular extracts will be cells derived 10 from human central nervous tissue or endocrine tissues. In particular, cellular extracts may be prepared from a particular region, including, but not limited to, the hippocampus, the cerebellum, the cerebrum, the cerebral cortex, the pituitary, the medulla, and the adrenal gland. Further, cellular extracts may be prepared from a particular primary cell isolate of central nervous system origin or the endocrine systems including, but not limited to, neurons, 15 astrocytes, and endocrine cells of the medulla. Alternatively, cellular extracts may be prepared from available cell lines, particularly cell lines of a neurological or endocrine origin. Cell lines contemplated herein include, but are not limited to, rat PC12 pheochromocytoma cells, AtT-20, GH3 and HIT cells.

A variety of methods can be used to obtain an extract of a cell. Cells can be disrupted 20 using either physical or chemical disruption methods. Examples of physical disruption methods include, but are not limited to, sonication and mechanical shearing. Examples of chemical lysis methods include, but are not limited to, detergent lysis and enzyme lysis. A skilled artisan can readily adapt methods for preparing cellular extracts in order to obtain extracts for use in the present methods.

Once an extract of a cell is prepared, the extract is mixed with SV2 protein or 25 fragment and other components of the assay under conditions in which association of the protein with the binding partner can occur, followed by the addition of LEV or an analog or derivative thereof. Alternatively, the LEV or an analog or derivative thereof may be added to the cellular extract before or at even time with the test agent or compound. A variety of 30 conditions can be used, the most preferred being conditions that closely resemble conditions found in the cytoplasm of a human cell. Features such as osmolarity, pH, temperature, and

the concentration of cellular extract used, can be varied to optimize the association of the protein with the binding partner.

After mixing under appropriate conditions, the bound complex is separated from the mixture. A variety of techniques can be utilized to separate the mixture. For example, antibodies specific to SV2A can be used to immunoprecipitate the binding partner complex. Alternatively, standard chemical separation techniques such as chromatography and density/sediment centrifugation can be used.

After removal of non-associated cellular constituents found in the extract, the binding partner can be dissociated from the complex using conventional methods. For example, dissociation can be accomplished by altering the salt concentration or pH of the mixture.

As discussed above, to aid in separating associated binding partner pairs from the mixed extract, the LBS can be immobilized on a solid support. For example, the LBS can be attached to a nitrocellulose matrix or acrylic beads. Attachment of the LBS to a solid support aids in separating peptide/binding partner pairs from other constituents found in the extract.

The identified binding partners can be either a single protein or a complex made up of two or more proteins. Alternatively, binding partners may be identified using a Far-Western assay according to the procedures of Takayama *et al.* (Methods Mol. Biol. 69:171-184. (1997)) or Sauder *et al.* (J. Gen. Virol. 77:991-996. (1996)) or identified through the use of epitope tagged proteins or poly-His fusion or GST fusion proteins.

Alternatively, mammalian cell-based protein-protein assays utilizing bioluminescence or fluorescence energy transfer (BRET and FRET, respectively) and the yeast two-hybrid system may be a tool for the identification of protein-protein interactions.

Another approach to identifying pharmacologically active compounds that act via the SV2 proteins is by analyzing the effects of such compounds on wild-type and SV2 knockout cell lines, tissues, and animals. For example, compounds of interest, which might have previously been identified by testing in genomic wild-type animal or tissue models of disease, or by screening against functional cellular assays, can be re-tested in equivalent or informative assays in cells, tissues or animals that have reduced or low levels of functional SV2 proteins, or which lack functional SV2 proteins altogether. Such knockdowns or knockouts might be obtained, for example, by using anti-sense or RNAi techniques, or by working with genomic knockout animals.

In some embodiments, compounds that inhibit N-type calcium channels in neurons of wild-type animals are identified, followed by testing the compounds under the same conditions in neurons that have their SV2 proteins knocked down using RNAi or antisense oligos targeted to the SV2 mRNA sequences, or, alternately, neurons from genomic SV2 knockout animals. The lack of an effect in the SV2 knockout neurons would be evidence that the compounds are having their effect via SV2 proteins.

In another embodiment, compounds with anticonvulsant properties are identified by testing their ability to inhibit epileptiform field potentials recorded in the CA3 area of wild-type rat hippocampal slices bathed in an epileptogenic medium containing increased potassium and lowered calcium. Compounds that exhibit anticonvulsant properties could then be tested in the same assay using SV2 knockout or knockdown hippocampal slices. If a lack of efficacy was observed in the slices without SV2 protein expression, this would strongly support an effect mediated by interactions with SV2 proteins.

In another embodiment, the effect of compounds or agents which bind to the LBS on presynaptic divalent cation storage can be studied in knockout or knockdown mice. In a particular embodiment, wild-type and SV2 knockout or knockdown mice are administered an amount of the compound or agent which binds to the LBS. Animals are sacrificed and brains are immediately removed and flash-frozen. Elemental imaging of thin freeze-dried cryosections is carried out and the elemental composition of the presynaptic nerve terminals is determined by electron probe x-ray microanalysis and elemental imaging of characteristic x-rays. An example of such a method is disclosed by Andrews *et al.* (Proc. Natl. Acad. Sci. USA 84(6):1713-1717 (1987)).

#### **IV. *In Vitro* Characterization of SV2**

The invention includes the functional characterization of the SV2 family of proteins. In one embodiment, the invention includes the cloning and expression of both the rat and human forms of the SV2 proteins SV2A, SV2B, SV2C and the related synaptic vesicle protein SVOP. In another embodiment, the invention further includes identification of the domain or domains comprising the LBS. In an additional embodiment, the invention includes discovery of possible multiple functions of the SV2 proteins, and of the effect(s) of levetiracetam and related ligands on these functions.

In an additional embodiment, the invention includes expression of the SV2 protein in a eukaryotic host cell for study of function. The protein might be expressed in it's native form, or as fusions with fluorescent or other peptidic tags, including epitope and affinity tags; mutant forms, or fragments of the protein might be expressed and studied, fusions between 5 the protein and homologous proteins might be expressed and studied. The heterologously expressed SV2 might be studied in-situ using electrophysiology, microscopy, or other techniques; or it might be expressed and purified in functional form from the eukaryotic using electrophysiology or other techniques.

In one particular embodiment, the SV2 protein, native or modified as above, might be 10 expressed in a eukaryotic host and purified. The protein might be purified and incorporated into artificial lipid vesicles, or artificial bilayer membranes for study. Possible transport functions of the SV2 protein might be studied by biochemical means, for instance measuring radioactively labeled substrate transport into or out of the vesicles. Another possible approach is to use electrophysiology to study such transport in purified protein incorporated 15 into synthetic vesicles or artificial lipid membranes.

In another particular embodiment, the invention includes the expression of the SV2 protein in a prokaryotic host, such as *E. coli*, and purification. In another particular embodiment, the invention includes the recombinant expression of the SV2 protein in a eukaryotic host, including yeast (*Saccharomyces cerevisie* or *Pichia pastoris*, for example), 20 COS-7, HEK293 and PC12a cells, and purification. In accordance with the present invention, polynucleotide sequences that encode SV2 proteins, fragments of the polypeptide, fusion proteins or functional equivalents thereof may be used to generate recombinant DNA molecules that direct the expression of SV2 protein in appropriate host cells. Due to the inherent degeneracy of the genetic code, other DNA sequences that encode substantially the 25 same or a functionally equivalent amino acid sequence may be used to clone and express SV2. As will be understood by those of skill in the art, it may be advantageous to produce SV2-encoding nucleotide sequences possessing non-naturally occurring codons. Codons preferred by a particular prokaryotic or eukaryotic host (Murray *et al.* Nuc. Acids Res. 17:477-508. (1989)) can be selected, for example, to increase the rate of SV2 expression or to 30 produce recombinant RNA transcripts having desirable properties, such as a longer half-life, than transcripts produced from naturally occurring sequence.

In another embodiment, SV2 proteins of the invention are recombinantly co-expressed in host cells with other proteins SV2 is normally associated with in synaptic vesicles. In a preferred embodiment, SV2 proteins are co-expressed with SNARE complex proteins including vesicle-associated VAMP/synaptobrevin, syntaxin and SNAP-25. In a 5 preferred embodiment, SV2A is recombinantly co-expressed in a host cell with recombinantly expressed synaptotagmin.

In another embodiment, the roles of glycosylation, phosphorylation and other natural or introduced protein modifications in SV2 protein function, stability and interaction are analyzed. Nucleotide sequences encoding SV2 proteins of the present invention can be 10 engineered using methods generally known in the art in order to alter sequences encoding SV2 proteins for a variety of reasons, including but not limited to; alterations which modify the cloning, processing, and/or expression of the gene product; alterations which modify the interaction of SV2 proteins with binding partners; alterations of the solubility and/or membrane insertion of SV2 proteins; and alterations which affect the LBS and its association 15 with ligands. DNA shuffling by random fragmentation and PCR reassembly of gene fragments and synthetic oligonucleotides may be used to engineer the nucleotide sequences. For example, site-directed mutagenesis may be used to insert new restriction sites, to alter glycosylation patterns, to change codon preference, to produce splice variants, or to introduce mutations, and so forth.

Upon exocytosis at the synapse, vesicles cluster at the pre-synaptic plasma membrane 20 and fuse in response to increased  $\text{Ca}^{2+}$  levels. Upon  $\text{Ca}^{2+}$  accumulation within the synapse, the binding of synaptotagmin to SV2A is inhibited and dimerization of two synaptotagmin  $\text{Ca}^{2+}$ -binding domains (C2B) is stimulated, which may play a role in organizing the SNARE 25 complex and promoting fusion. At low  $\text{Ca}^{2+}$ , the fusion of vesicles is inhibited because SV2A is still attached to the synaptotagmin complex. Binding of synaptotagmin to other 30 proteins, including the ATPase VCP, the SNARE protein SNAP-25 and syntaxin, is  $\text{Ca}^{2+}$ -dependent (Augustine, 2001). In order to shed light on this exocytosis mechanism and define more precisely the role of SV2A in the fusion process, changes in protein levels within these complexes in response to modulation of the LBS are assayed. In particular embodiments, the ability of LBS ligands to modulate the interactions between SV2A and the synaptotagmin-SNARE complex and to assess which stage of the complex assembly and which partners are

modulated by the binding to SV2A of LEV, analogs or derivatives thereof, or compounds or agents which compete with LEV for binding to the LBS. In one such embodiment, protein stoichiometry in the complex after ligand addition is analyzed using antibodies specific for the identified SV2A partners and a combination of immunoprecipitation and recombinant

5 GST-fusion protein affinity chromatography.

In another such embodiment, mass spectrometry and/or surface plasmon resonance are used to detect the effects of LBS ligands on the interactions between SV2A and its partner (e.g. synaptotagmin) or short peptides derived from binding domains. In another particular embodiment, biochemical approaches are used to demonstrate if LBS ligands compete with

10 bivalents (such as  $\text{Ca}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Zn}^{2+}$ ) and inhibit their interactions with SV2A and/or synaptotagmin. In another particular embodiment, the role of the SV2 proteins in synaptic vesicle fusion and recycling is analyzed by the creation of PC12a cell lines, primary neuronal cultures, chromaffin cells and other cell lines or primary isolates expressing fusion constructs between the SV2 proteins and GFP. In one such embodiment, these cell lines are analyzed

15 by fluorescence microscopy tracking of SV2 complexes and synaptic vesicle exocytosis and trafficking, and the effects of treatments with LBS ligands on these events. The cell types described above can also be used to measure vesicle fusion and exocytosis (using encapsulated dye into the vesicles or measuring the release of labeled neurotransmitters) and the ability of LBS ligands to modulate these activities.

20 In other embodiments of characterizing SV2 proteins and its binding partners, enrichment of the entire multi-protein complex is achieved by affinity-based methods using GST-fusion SV2 or anti-SV2 antibodies. In a particular embodiment, SV2A is overexpressed in PC12 cells with a GST tag and, together with its partners, immunoprecipitated by an antibody against the tag. In a related embodiment, SV2A is immobilized onto agarose beads

25 using a GST or poly-histidine tag. In a preferred embodiment, synaptic vesicle extracts, cell extracts or brain extracts are incubated with the beads, SV2A is cleaved off and eluted proteins are resolved by 1D or 2D gels and analyzed. In a further embodiment, identification of these proteins is used to search databases for novel putative interacting partners. In another embodiment, the yeast two-hybrid (Y2H) system or mammalian cell-based protein-

30 protein assays are used for the identification of protein-protein interactions within living organisms to confirm SV2 binding partners found by the affinity-based methods and to define

the specific protein domain interactions using known cDNAs.

Antibodies specific for SV2 proteins may be produced by inoculation of an appropriate animal with the polypeptide or an antigenic fragment. Antibodies specific for the LBS may be produced by inoculation with full-length SV2 protein or a fragment comprising 5 the LBS. An antibody is specific for the particular SV2 if it is produced against an epitope of the polypeptide and binds to at least part of the natural or recombinant protein. Monoclonal and/or polyclonal antibodies specific for SV2 or for the LBS may be produced by any of a number of methods which are well known in the art for antibody production, such as those taught by Harlow and Lane (Antibodies: A Laboratory Manual. Cold Spring Harbor 10 Laboratory, Cold Spring Harbor, New York. (1988)). SV2 peptides for antibody induction do not require biological activity; however peptides must be immunogenic. Peptides used to induce specific antibodies may have an amino acid sequence consisting of at least five amino acids, preferably at least 10 amino acids. They should mimic a portion of the amino acid sequence of the natural protein and may contain the entire amino acid sequence of a small, 15 naturally occurring molecule. Short stretches of SV2 amino acids may be fused with those of another protein such as keyhole limpet hemocyanin and antibody produced against the chimeric molecule. Antibody production includes not only the stimulation of an immune response by injection into animals, but also analogous steps in the production of synthetic antibodies or other specific-binding molecules such as the screening of recombinant 20 immunoglobulin libraries (see e.g. Orlandi *et al.* Proc. Nat. Acad. Sci. USA 86:3833-3837. (1989); Huse *et al.* Science 256:1275-1281. (1989)) or the *in vitro* stimulation of lymphocyte populations. Current technology (Winter G. and Milstein C. (1991) Nature 349:293-299) provides for a number of highly specific binding reagents based on the principles of antibody formation. These techniques may be adapted to produce molecules specifically binding SV2 25 or the LBS.

In a particular embodiment, the present invention includes the human SV2C protein of SEQ ID NO: 6 and the nucleic acid molecule encoding it (SEQ ID NO: 5), as well as allelic variants and functional equivalents thereof. The invention further includes identification of the *in vivo* distribution of the SV2C protein, including, but not limited to, 30 within the central nervous system, peripheral nervous system and endocrine cells and tissues. The invention further includes identification of ligands and/or binding partners of the SV2C

protein. The invention further includes elucidation of the function of the SV2C protein.

## V. SV2 Expression in Disease

The invention includes elucidating the expression of SV2 proteins in relation to specific neurological diseases. In a particular embodiment, antibodies specific for SV2A are used to probe brain tissue in a regional specific manner within the brain, spinal cord and neuroendocrine tissues or cells such as chromaffin cells of control animals and animals mimicking epilepsy, epileptogenesis, Parkinson's disease and cognition deficits, other CNS disorders (see above) and endocrinopathy and adrenal medulla-related diseases. In another embodiment, the invention includes the elucidation of the relationship of all SV2 protein isoforms to the pathologies described above, including alterations or switching of isoforms. In a preferred embodiment DNA microarrays are probed for the expression of SV2 protein coding sequences, and changes thereof, in relation to different neurological diseases. An example of using DNA microarrays for determining expression of a particular nucleic acid sequence can be found in U.S. Patent 5,900,882. In another preferred embodiment, changes in regional or global SV2 protein expression in relation to a neurological disorder associated with synaptic vesicle function is validated by quantitative PCR (qPCR).

In another embodiment, knockout mice are analyzed for the presence of the LBS. In a preferred embodiment, purified synaptic vesicles from mice with the lethal SV2A knockout phenotype, SV2B or double KO SV2A/B are purified and analyzed for the presence of the LBS and for substrate and/or ion uptake in comparison with synaptic vesicles from wild-type mice.

In a particular embodiment, comparisons are made of protein expression levels in synaptic vesicles purified from healthy and diseased animals including, but not limited to, pathologies described above, for example, for protein mapping of synaptic vesicles for the detection of disease-related proteins. In a particular embodiment, comparison of 1D and/or 2D gels of synaptic vesicles derived from the healthy and the diseased states are used to identify proteins that are up- or down-regulated in a disease-specific manner. In another embodiment, targets are identified by comparison of the proteome of synaptic vesicles from wild-type with that of SV2 knock-out mice or double-stranded RNA-induced interference (RNAi; Krichevsky *et al.*, Proc. Nat. Acad. Sci. USA 99(18):11926-11929, (2002)) cultured

neurons. In another embodiment, the invention includes performing RNAi or antisense nucleotides in primary neuronal cultures, cultured neurons or PC12 cells to inhibit or eliminate SV2 expression.

## 5 VI. Determination of the LBS Location on the SV2 Protein

A number of methods are employed in the determination of the location of the LBS. The LBS may be comprised of a contiguous segment of amino acid residues, or it may be a 3 dimensional structure comprised of amino acid sequences present on one or more extracellular or intracellular loops or domains. In addition, the LBS may be dependent upon 10 the glycosylation of the SV2 protein or may not require glycosylation of the SV2 protein.

In a particular embodiment, radioligands are used to specifically photoaffinity-label the LBS. In a particular embodiment, the site of covalent attachment of the radioligand is determined by purifying and sequencing the proteolytic fragment from photoaffinity labeled synaptic vesicles with SV2A-antibody affinity chromatography or immunoprecipitation and 15 mass spectrometry.

In particular embodiments for the identification of protein domains involved in the interactions between LBS ligands and the SV2A protein fragments of SV2 proteins, or SV2 proteins with amino acid deletions, additions or substitutions are analyzed for effects on binding. In a preferred embodiment, selected residues will be modified by site directed 20 mutagenesis of the cDNA. In another embodiment, domains are exchanged between SV2 isoforms and structural features of isoforms that are important for ligand recognition are identified. In an example of this embodiment, the N-terminal domain of SV2A is replaced with the shorter equivalent region of SV2B to determine the effect on LBS ligand binding. In another example of this embodiment, a series of swaps are made between regions of SV2A 25 and regions of SV2B, to determine the effect on ligand binding. Such swaps might include large regions of each protein, containing for example, multiple transmembrane regions, as well as small regions of the protein, including for example individual transmembrane regions.

In another embodiment, the three-dimensional structure of the SV2 protein (or selected binding domains) is analyzed using NMR spectroscopy or x-ray crystallography or 30 circular dichroism or infrared spectroscopy utilizing pure SV2A with at least binding activity maintained for the revelation of resolution of the topology of LBS sites and design of new

drugs to fit that receptor. If the binding domain upon investigation requires an hydrophobic environment then the protein must be solubilized in a detergent such as dodecylmaltoside or derivatives (see Examples). Purified protein can be crystallized by methods known in the art, for example, by methods disclosed by A. McPherson in "Preparation and Analysis of Protein

5 Crystals" (John Wiley and Sons, New York, (1982)). Alternatively, SV2 proteins of the present invention may also be crystallized by vapor diffusion and vapor diffusion apparatus used in the art may be readily employed in the processes of the present invention. Such apparatus are disclosed in, for example, U.S. Pat. Nos. 4,886,646; 5,096,676; 5,130,105; 10 5,221,410 and 5,400,741, the disclosure of which are herein incorporated by reference. X-ray crystallography determination of SV2 protein structure as well as its association with ligands and/or binding partners can be performed using methods and imaging systems as disclosed in U.S. Patent No. 5,978,444, for example.

In some embodiments, SV2 proteins, including isoforms SV2A, SV2B are SV2C, are recombinantly expressed in host cell lines to screen a diverse set of compounds or agents in 15 binding assays for each isoform. Compounds or agents that interact with the SV2A isoform are analyzed for interaction with other SV2 isoforms. In another embodiment, binding experiments are performed to test several reference drugs, AEDs, steroids and to compare the kinetics of binding between native LBS, human and rat recombinant SV2A.

## 20 VII. Uses for Agents on the Invention

The invention includes the use of the compounds or agents identified by methods of the invention for the modulation of SV2 protein. Compounds or agents of the invention can be used to modulate synaptic vesicle function; in particular to modulate disorders associated with synaptic vesicle function, or disorders which might be improved by affecting some 25 aspect of synaptic vesicle function, or also to modulate synaptic vesicle function in order to correct disorders of pre-synaptic function, or disorders of neuronal signaling that can be fixed by compensatory changes in synaptic vesicle function. As used herein, a compound or agent is said to modulate synaptic vesicle function if it is capable of up- or down-regulating at least one function of at least one component of a synaptic vesicle, or the pre-synaptic systems 30 which synaptic vesicles interact with.

In a preferred embodiment, the agent or compound is LEV or an analog or derivative

thereof. In another preferred embodiment, the compound or agent binds to the levetiracetam binding site of an SV2 protein. In still another preferred embodiment, the compound or agent competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site. In yet another preferred embodiment, agents of the invention for 5 the treatment of neurological disorders include N-alkylated 2-oxo-pyrrolidine derivatives, N-alkylated 2-oxo-piperidinyl derivatives, and N-alkylated 2-oxo-azepanyl derivatives as described above.

In a preferred embodiment, the compound or agent is an anti-SV2 antibody or fragment thereof, including those that bind to the levetiracetam binding site of SV2 protein 10 and may be a polyclonal antibody or a monoclonal antibody. In related preferred embodiments, the antibody fragment is an Fab fragment, Fab' fragment, F(ab')<sub>2</sub> fragment or an scFv fragment, whereas the monoclonal antibody is a chimeric antibody, humanized antibody, or a human antibody.

In a preferred embodiment, the invention includes the modulation at least one 15 function or activity of a SV2 protein in a cell, for example, by exposing the cell to a compound or agent that binds to the levetiracetam binding site of the SV2 protein. In particular embodiments, modulation at least one function or activity of a SV2 protein in a cell includes exposure of the cell to the compound or agent *in vitro*, *in vivo*, *in situ* and *ex vivo*. As used herein, modulation of a function of SV2 includes, but is not limited to modulation of 20 the transport of ions or other natural substrates across the membrane of the synaptic vesicle, modulation of the binding of an SV2 protein to a natural ligand thereof, modulation of the binding of an SV2 protein to a binding partner as described above, and remodulation of synaptic vesicle formation, fusion, regulation or function.

In a preferred embodiment, the modulation of SV2 protein in a cell includes 25 modulating synaptic vesicle function in the cell. As used herein, synaptic vesicle functions which may be modulated by compounds or agents identified by the methods of the invention include, but are not limited to, formation of synaptic vesicles in the presynaptic neuron, fusion of synaptic vesicles with other synaptic vesicles or the synaptic membrane, recycling or turnover of synaptic vesicles, association of synaptic vesicles with the presynaptic grid, 30 and neurotransmitter release, association with proteins from the extracellular matrix (laminin-1, etc.) and post-synaptic densities.

In particular embodiments, exposure of the cell to a compound or agent of the invention which modulates at least one function or activity of a SV2 protein in a cell is carried out under conditions where the concentration of monovalent and/or divalent cations in the environment of the cell is controlled. In preferred embodiments, the divalent cation is at least one of  $\text{Ca}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Mn}^{2+}$ ,  $\text{Fe}^{2+}$  and  $\text{Cu}^{2+}$ . In preferred embodiments, the monovalent cation is  $\text{K}^+$ . In a particular embodiment, exposing the cell to a compound or agent which binds to the levetiracetam binding site is carried out under conditions with a low monovalent and/or divalent cation concentration, or less than about 1  $\mu\text{M}$ . In another particular embodiment, exposing the cell to a compound or agent which binds to the levetiracetam binding site is carried out under conditions with a physiological monovalent and/or divalent cation concentration, or between about 1  $\mu\text{M}$  and about 1000  $\mu\text{M}$ . In yet another particular embodiment, exposing the cell to a compound or agent which binds to the levetiracetam binding site is carried out under conditions with a high monovalent and/or divalent cation concentration, or more than at least about 1000  $\mu\text{M}$ .

15

### **VIII. Treatment Of Neurological Disorders**

Compounds or agents identified by the methods of the invention can be used in an effective amount to treat neurological disorders associated with synaptic vesicle function. In a particular embodiment, treatment with the compound or agent modulates a neurological disorder. In a preferred embodiment, the neurological disorder is a seizure disorder. In another preferred embodiment, the neurological disorder is selected from the group consisting of Parkinson's disease, Parkinson's dyskinesias, migraine, Alzheimer's disease, neuropathic pain, essential tremor, and cognitive disorders. In a highly preferred embodiment, the neurological disorder is epilepsy. In another highly preferred embodiment, treatment with the compound or agent enhances cognitive function.

In a preferred embodiment, the agent or compound is LEV or an analog or derivative thereof. In another preferred embodiment, the compound or agent binds to the levetiracetam binding site of an SV2 protein. In still another preferred embodiment, the compound or agent competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site. In yet another preferred embodiment, agents of the invention for the treatment of neurological disorders include N-alkylated 2-oxo-pyrrolidine derivatives, N-

alkylated 2-oxo-piperidinyl derivatives, and N=alkylated 2-oxo-azepanyl derivatives as described above.

In a preferred embodiment, the compound or agent is an anti-SV2 antibody or fragment thereof, including those that bind to the levetiracetam binding site of SV2 protein 5 and may be a polyclonal antibody or a monoclonal antibody. In related preferred embodiments, the antibody fragment is an Fab fragment, Fab' fragment, F(ab')<sub>2</sub> fragment or an scFv fragment, whereas the monoclonal antibody is a chimeric antibody, humanized antibody, or a human antibody.

As used herein, a subject can be any mammal, so long as the mammal is in need of 10 modulation of function or activity of a SV2 protein mediated by a compound or agent identifiable by a method of the invention. The term mammal is defined as an individual belonging to the class Mammalia. The invention is particularly useful in the treatment of human subjects.

As used herein, an "effective amount" is an amount of a substance, compound or 15 agent which is effective to inhibit, reduce, ameliorate, modulate or control at least one symptom or effect of a disease, condition or another administered substance, compound or agent either *in vivo*, *ex vivo*, or *in vitro*. Further as used herein, an "effective amount" is an amount of a substance, compound or agent which is effective to enhance at least one cognitive function *in vivo*.

As used herein, an agent is said to modulate a neurological disorder when the agent 20 reduces the degree or severity of at least one symptom the neurological disorder. For instance, seizures in epilepsy may be prevented; the amplitude, magnitude or severity of seizures may be reduced, or the frequency of the occurrence of seizures may be reduced by the administration of compounds or agents which up- or down-regulate or modulate in some 25 way the expression or at least one activity of a SV2 protein of the invention.

The compounds or agents identified by the methods of the present invention can be 30 provided alone, or in combination with other compounds or agents that modulate a particular pathological process. For example, a compound or agent of the present invention can be administered in combination with other known drugs. As used herein, two agents are said to be administered in combination when the two agents are administered simultaneously or are administered independently in a fashion such that the agents will act at the same time. In a

particular embodiment of the invention; the compounds or agents identified by the methods of the present invention can be provided in combination with compounds or agents that modulate GABAergic pathways in the brain. In another embodiment, the compounds of the invention are administrated together with amantadine for combined treatment of L-DOPA and tardive dyskinesia.

5 The compounds or agents of the present invention can be administered via parenteral, subcutaneous, intravenous, intramuscular, intraperitoneal, epidural, transdermal, topical, or mucosal routes, or combinations thereof. The dosage administered will be dependent upon the age, health, and weight of the recipient, kind of concurrent treatment, if any, frequency of 10 treatment, and the nature of the effect desired. Drug solubility and the site of absorption are factors which should be considered when choosing the route of administration of a therapeutic agent.

15 The present invention further includes compositions containing one or more compounds or agents which modulate expression or at least one activity of a SV2 protein of the invention. While individual needs vary, determination of optimal ranges of effective amounts of each component is within the skill of the art. Typical dosages comprise about 0.1 to about 100 mg/kg body weight. The preferred dosages comprise about 5 to about 80 mg/kg body weight. More preferred dosages comprise about 10 to about 60 mg/kg body weight. The most preferred dosages comprise about 20 to about 40 mg/kg body weight.

20 In addition to the pharmacologically active agent, the compositions of the present invention may contain suitable pharmaceutically acceptable carriers comprising excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically for delivery to the site of action.

25 The compounds or agents may be formulated for parenteral administration by injection, *e.g.*, by bolus injection or continuous infusion. Suitable formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form, for example, water-soluble salts. In addition, suspensions of the active compounds as appropriate oily injection suspensions may be administered. Suitable lipophilic solvents or vehicles include fatty oils, for example, sesame oil, or synthetic fatty acid esters, for example, 30 ethyl oleate or triglycerides. Aqueous injection suspensions may contain substances which increase the viscosity of the suspension include, for example, sodium carboxymethyl

cellulose, sorbitol, and/or dextran. Liposomes can also be used to encapsulate the agent for delivery into the cell. Formulations for injection may be presented in unit dosage form, e.g., in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may 5 contain formulatory agents such as suspending, stabilizing and/or dispersing agents.

Alternatively, the active ingredient may be in powder form for constitution with a suitable vehicle, e.g., sterile pyrogen-free water, before use.

Mucosal routes of administration include, but are not limited to, oral, rectal and nasal administration. Preparations for mucosal administrations are suitable in various formulations.

10 If the compound or agent is water-soluble, then it may be formulated in an appropriate buffer, for example, phosphate buffered saline or other physiologically compatible solutions, preferably sterile. Alternatively, if the resulting complex has poor solubility in aqueous solvents, then it may be formulated with a non-ionic surfactant such as Tween, or polyethylene glycol. Thus, the compounds and their physiologically acceptable solvates may 15 be formulated for administration by inhalation or insufflation (either through the mouth or the nose) or oral, buccal, parenteral, or rectal administration or, in the case of tumors, directly injected into a solid tumor. For administration by inhalation, the compounds for use according to the present invention are conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebulizer, with the use of a suitable propellant, e.g., 20 dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of, e.g., gelatin for use in an inhaler or insufflator may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

25 For oral administration, the pharmaceutical preparation may be in liquid form, for example, solutions, syrups or suspensions, or may be presented as a drug product for reconstitution with water or other suitable vehicle before use. Such liquid preparations may be prepared by conventional means with pharmaceutically acceptable additives such as suspending agents (e.g., sorbitol syrup, cellulose derivatives or hydrogenated edible fats); 30 emulsifying agents (e.g., lecithin or acacia); non-aqueous vehicles (e.g., almond oil, oily esters, or fractionated vegetable oils); and preservatives (e.g., methyl or propyl-p-

hydroxybenzoates or sorbic acid). The pharmaceutical compositions may take the form of,

for example, tablets or capsules prepared by conventional means with pharmaceutically acceptable excipients such as binding agents (e.g., pregelatinized maize starch, polyvinyl pyrrolidone or hydroxypropyl methylcellulose); fillers (e.g., lactose, microcrystalline

5 cellulose or calcium hydrogen phosphate); lubricants (e.g., magnesium stearate, talc or silica); disintegrants (e.g., potato starch or sodium starch glycolate); or wetting agents (e.g., sodium lauryl sulphate). The tablets may be coated by methods well-known in the art. Preparations for oral administration may be suitably formulated to give controlled release of the active compound.

10 For buccal administration, the compositions may take the form of tablets or lozenges formulated in conventional manner.

The compounds or agents may also be formulated in rectal compositions such as suppositories or retention enemas, e.g., containing conventional suppository bases such as cocoa butter or other glycerides.

15 In addition to the formulations described previously, the compounds or agents may also be formulated as a depot preparation. Such long acting formulations may be administered by implantation (for example, subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the compounds may be formulated with suitable polymeric or hydrophobic materials (for example, as an emulsion in an acceptable oil) or ion 20 exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt. Liposomes and emulsions are well known examples of delivery vehicles or carriers for hydrophilic drugs.

25 In practicing the methods of this invention, the compounds or agents of this invention may be used alone or in combination, or in combination with other therapeutic or diagnostic agents. In certain preferred embodiments, the compounds of this invention may be co-administered along with other compounds or agents typically prescribed for these conditions according to generally accepted medical practice such as anticonvulsives. The compounds of this invention can be utilized *in vivo*, ordinarily in mammals, such as humans, sheep, horses, cattle, pigs, dogs, cats, rats and mice, or *in vitro*.

## IX. Gene Therapy

SV2 proteins used in treatment can be generated endogenously in the subject, in treatment modalities often referred to as "gene therapy." In a specific embodiment, nucleic acids comprising sequences encoding SV2 proteins or functional derivatives thereof, are administered to treat, inhibit or prevent a neurological disease or disorder associated with aberrant synaptic function, by way of gene therapy. Gene therapy refers to therapy performed by the administration to a subject of an expressed or expressible nucleic acid. In this embodiment of the invention, the nucleic acids produce their encoded SV2 protein that mediates a therapeutic effect.

Any of the methods for gene therapy available in the art can be used according to the present invention. Exemplary methods are described below.

For general reviews of the methods of gene therapy, see Goldspiel *et al.*, Clinical Pharmacy 12:488-505. (1993); Wu and Wu, Biotherapy 3:87-95. (1991); Tolstoshev, Ann. Rev. Pharmacol. Toxicol. 32:573-596. (1993); Mulligan, Science 260:926-932. (1993); and Morgan and Anderson, Ann. Rev. Biochem. 62:191-217. (1993); TIBTECH 11(5):155-215. (1993)). Methods commonly known in the art of recombinant DNA technology which can be used are described in Ausubel *et al.*, eds., Current Protocols in Molecular Biology, John Wiley & Sons, NY (1993); and Kriegler, Gene Transfer and Expression, A Laboratory Manual, Stockton Press, NY (1990).

In a preferred aspect, the compound comprises nucleic acid sequences encoding an SV2 protein, said nucleic acid sequences being part of expression vectors that express the SV2 protein or fragments or chimeric proteins thereof in a suitable host. In particular, such nucleic acid sequences have promoters operably linked to the SV2 protein coding region, said promoter being inducible or constitutive, and, optionally, tissue-specific. In another particular embodiment, nucleic acid molecules are used in which the SV2 protein coding sequences and any other desired sequences are flanked by regions that promote homologous recombination at a desired site in the genome, thus providing for intrachromosomal expression of the antibody nucleic acids (Koller *et al.*, Proc. Natl. Acad. Sci. USA 86:8932-8935. (1989); Zijlstra *et al.*, Nature 342:435-438. (1989)).

Delivery of the nucleic acids into a patient may be either direct, in which case the

patient is directly exposed to the nucleic acid or nucleic acid-carrying vectors, or indirect, in which case, cells are first transformed with the nucleic acids *in vitro*, then transplanted into the patient. These two approaches are known, respectively, as *in vivo* or *ex vivo* gene therapy.

5 In a specific embodiment, gene therapy vectors can be delivered *in vivo* to a subject by, for example, intravenous injection, local administration (see U.S. Pat. No. 5,328,470) or by stereotactic injection (see *e.g.*, Chen *et al.* Proc. Natl. Acad. Sci. USA 91:3054-3057. (1994)). The pharmaceutical preparation of the gene therapy vector can include the gene 10 therapy vector in an acceptable diluent, or can comprise a slow release matrix in which the gene delivery vehicle is imbedded. Alternatively, where the complete gene delivery vector can be produced intact from recombinant cells, *e.g.*, retroviral vectors, the pharmaceutical preparation can include one or more cells which produce the gene delivery system.

Direct administration of the nucleic acid sequences for expression of encoded SV2 protein *in vivo* can be accomplished by any of numerous methods known in the art, *e.g.*, by 15 constructing them as part of an appropriate nucleic acid expression vector and administering them so that they become intracellular, *e.g.*, by infection using defective or attenuated retroviral vectors or other viral vectors (see U.S. Pat. No. 4,980,286), or by direct injection of naked DNA, or by use of microparticle bombardment (*e.g.*, a gene gun; Biolistic, Dupont), or coating with lipids or cell-surface receptors or transfecting agents, encapsulation in 20 liposomes, microparticles, or microcapsules, or by administering them in linkage to a peptide which is known to enter the nucleus, by administering it in linkage to a ligand subject to receptor-mediated endocytosis (see, *e.g.*, Wu *et al.*, J. Biol. Chem. 262:4429-4432. (1987)) (which can be used to target cell types specifically expressing the receptors), etc. In another embodiment, nucleic acid-ligand complexes can be formed in which the ligand comprises a 25 fusogenic viral peptide to disrupt endosomes, allowing the nucleic acid to avoid lysosomal degradation. In yet another embodiment, the nucleic acid can be targeted *in vivo* for cell specific uptake and expression, by targeting a specific receptor (see, *e.g.*, PCT Publications WO 92/06180 dated Apr. 16, 1992 (Wu *et al.*); WO 92/22635 dated Dec. 23, 1992 (Wilson *et al.*); WO 92/20316 dated Nov. 26, 1992 (Findeis *et al.*); WO 93/14188 dated Jul. 22, 1993 30 (Clarke *et al.*); and WO 93/20221 dated Oct. 14, 1993 (Young)). Alternatively, the nucleic acid can be introduced intracellularly and incorporated within host cell DNA for expression,

by homologous recombination (Koller *et al.*, Proc. Natl. Acad. Sci. USA 86:8932-8935. (1989); Zijlstra *et al.*, Nature 342:435-438. (1989)).

In a specific embodiment, viral vectors that contain nucleic acid sequences encoding an SV2 protein of the invention are used. For example, a retroviral vector can be used (see 5 Miller *et al.*, Meth. Enzymol. 217:581-599. (1993)). These retroviral vectors have been to delete retroviral sequences that are not necessary for packaging of the viral genome and integration into host cell DNA. The nucleic acid sequences encoding the antibody to be used in gene therapy are cloned into one or more vectors, which facilitates delivery of the gene into a patient. More detail about retroviral vectors can be found in Boesen *et al.* (Biotherapy 10 6:291-302. (1994)), which describes the use of a retroviral vector to deliver the mdrl gene to hematopoietic stem cells in order to make the stem cells more resistant to chemotherapy. Other references illustrating the use of retroviral vectors in gene therapy are: Clowes *et al.*, J. Clin. Invest. 93:644-651. (1994); Kiem *et al.*, Blood 83:1467-1473. (1994); Salmons *et al.*, Human Gene Therapy 4:129-141. (1993); and Grossman *et al.*, Curr. Opin. in Genetics and 15 Devel. 3:110-114. (1993).

Adenoviruses are other viral vectors that can be used in gene therapy. In a preferred embodiment, adenovirus vectors are used. Adenoviruses have the advantage of being capable of infecting non-dividing cells. Kozarsky *et al.*, Current Opinion in Genetics and Development 3:499-503. (1993) present a review of adenovirus-based gene therapy. Bout *et* 20 *al.*, Human Gene Therapy 5:3-10. (1994) demonstrated the use of adenovirus vectors to transfer genes to the respiratory epithelia of rhesus monkeys. Other instances of the use of adenoviruses in gene therapy can be found in Rosenfeld *et al.*, Science 252:431-434. (1991); Rosenfeld *et al.*, Cell 68:143-155. (1992); Mastrangeli *et al.*, J. Clin. Invest. 91:225-234. (1993); PCT Publication WO 94/12649; and Wang, *et al.*, Gene Therapy 2:775-783. (1995).

25 Adeno-associated virus (AAV) has also been proposed for use in gene therapy (Walsh *et al.*, Proc. Soc. Exp. Biol. Med. 204:289-300. (1993); U.S. Pat. No. 5,436,146).

Another approach to gene therapy involves transferring a gene to cells in tissue culture by such methods as electroporation, lipofection, calcium phosphate mediated transfection, or viral infection. Usually, the method of transfer includes the transfer of a 30 selectable marker to the cells. The cells are then placed under selection to isolate those cells that have taken up and are expressing the transferred gene. Those cells are then delivered to a

patient.

In this embodiment, the nucleic acid is introduced into a cell prior to administration *in vivo* of the resulting recombinant cell. Such introduction can be carried out by any method known in the art, including, but not limited to transfection, electroporation, microinjection,

5 infection with a viral or bacteriophage vector containing the nucleic acid sequences, cell fusion, chromosome-mediated gene transfer, microcell-mediated gene transfer, spheroplast fusion, etc. Numerous techniques are known in the art for the introduction of foreign genes into cells (see, *e.g.*, Loeffler and Behr, *Meth. Enzymol.* 217:599-618. (1993); Cohen *et al.*, *Meth. Enzymol.* 217:618-644. (1993); Cline, *Pharmac. Ther.* 29:69-92. (1985)) and may be used in accordance with the present invention, provided that the necessary developmental and physiological functions of the recipient cells are not disrupted. The technique should provide for the stable transfer of the nucleic acid to the cell, so that the nucleic acid is expressible by the cell and preferably heritable and expressible by its cell progeny.

10 The resulting recombinant cells can be delivered to a patient by various methods known in the art. Recombinant blood cells (*e.g.*, hematopoietic stem or progenitor cells) are preferably administered intravenously. The amount of cells envisioned for use depends on the desired effect, patient state, etc., and can be determined by one skilled in the art.

15 Cells into which a nucleic acid can be introduced for purposes of gene therapy encompass any desired, available cell type, and include but are not limited to epithelial cells, 20 endothelial cells, keratinocytes, fibroblasts, muscle cells, endocrine cells, hepatocytes; blood cells such as T lymphocytes, B lymphocytes, monocytes, macrophages, neutrophils, eosinophils, megakaryocytes, granulocytes; various stem or progenitor cells, in particular hematopoietic stem or progenitor cells, *e.g.*, as obtained from bone marrow, umbilical cord blood, peripheral blood, fetal liver, *etc.* In a preferred embodiment, the cells used for gene 25 therapy is autologous to the patient.

20 In an embodiment in which recombinant cells are used in gene therapy, nucleic acid sequences encoding an antibody are introduced into the cells such that they are expressible by the cells or their progeny, and the recombinant cells are then administered *in vivo* for therapeutic effect. In a specific embodiment, stem or progenitor cells are used. Any stem 30 and/or progenitor cells which can be isolated and maintained *in vitro* can potentially be used in accordance with this embodiment of the present invention (see *e.g.* PCT Publication WO

94/08598, dated Apr. 28, 1994; Stemple and Anderson, *Cell* 71:973-985. (1992); Rheinwald, *Meth. Cell Biol.* 21A:229. (1980); and Pittelkow and Scott, *Mayo Clinic Proc.* 61:771. (1986)).

5 In a specific embodiment, the nucleic acid to be introduced for purposes of gene therapy comprises an inducible promoter operably linked to the coding region, such that expression of the nucleic acid is controllable by controlling the presence or absence of the appropriate inducer of transcription.

#### X. Uses for Biotinylated Ligands

10 The present invention provides nonradioactive labelled SV2A/LBS ligands containing a biotin tag. Such biotinylated ligands are useful in screening assays with no radioactive waste and higher throughput.

15 As an example, biotinylated derivatives of SV2A/LBS ligands can be used in screening assays (e.g. binding) with native brain membranes or SV2 expressed in cell lines for the discovery of more potent structures. The amount of biotin tag bound to SV2A can be quantified using streptavidin-fluorescein or avidin derivatives.

Biotinylated ligands are also useful for assessing the conformational state of SV2 after solubilization, immunoaffinity purification, and chromatography.

20 Moreover, the present invention provides photoactivable versions of the ligands for labeling and detection in biological samples. The photoactivable biotinylated ligands may also be used to localize and purify SV2 from tissues, isolated cells, subcellular fractions and membranes. The photoactivable biotinylated ligands could also be used for SV2 cross-linking and identification of binding domains of LBS ligands.

#### 25 XII. Solubilizing SV2 and Affinity Purification

The present invention provides a method for solubilizing SV2/LBS proteins comprising treating membranes with a detergent. The membrane proteins solubilized by the present method remain active as evaluated by binding assays and protein-protein interaction studies.

30 Briefly, the method comprised incubating membranes, as an example rat brain membranes, in solubilization buffer containing the detergent n-dodecyl- $\beta$ -D-maltoside for

about two hours at about 4°C. The incubated solution was subsequently centrifuged to collect the soluble SV2 protein, specifically the SV2A protein, from the supernatant.

Presence of the soluble SV2A protein in the supernatant was confirmed by western blot analysis using anti-SV2A antibodies. The binding activity of the soluble SV2A protein in the supernatant was determined through binding experiments with ligands known to bind SV2A, such as levetiracetam and ucb 30889.

Other detergents such as the analogs of n-dodecyl- $\beta$ -D-maltoside, for example, n-octyl, n-nonyl, n-decyl, n-undecyl- $\beta$ -D-maltoside could also be used. In fact, preliminary data confirmed that the soluble protein obtained from solubilizing membranes with these detergents retains its binding activity.

The present invention also provides a method of affinity purification of the soluble SV2 protein and identification of putative SV2A partners. Briefly, affinity purification comprised incubating the supernatants from the solubilized membranes with anti-SV2A antibodies overnight at about 4°C. The mixture was then incubated by rotation with protein A-Sepharose beads in buffer for about an hour at about 4°C. The resin was washed several times with an appropriate buffer and the fractions containing the immunopurified SV2A protein were collected.

To detect the presence of binding partners of SV2A after affinity purification, a western blot analysis of the immunopurified fractions was performed to detect the presence of synaptotagmin (Figure 22)

The present invention provides a method to purify a membrane-associated protein comprising solubilizing a membrane sample containing the protein with a detergent to form a solubilized complex and isolating the solubilized complex in a functional form. The detergent could be n-dodecyl- $\beta$ -D-maltoside or derivatives thereof. The protein can then be isolated using an immunoaffinity technique.

The protein purified by the present method can be used to perform structural studies on the protein such as NMR, X-ray crystallography, Infrared spectroscopy, Circular dichroism and other methods well known in the art. The present invention also provides a method of performing SV2 protein interaction studies and for detecting peptides, molecules, and compounds that inhibit or promote the interactions between SV2 and a putative partner. The present invention can be used to identify SV2 binding partners.

The present invention could be used to solubilize SV2A, SV2B and SV2C membrane associated proteins and to affinity purify them for structural studies and for identifying binding partners.

5 Without further description, it is believed that one of ordinary skill in the art can, using the preceding description and the following illustrative examples, make and utilize the compounds of the present invention and practice the claimed methods. The following working examples therefore, specifically point out preferred embodiments of the present invention, and are not to be construed as limiting in any way the remainder of the disclosure.

10

## EXAMPLES

### Example 1. Development of a Levetiracetam Analog for Binding Studies

LEV has been shown to bind to a specific binding site located preferentially in the brain (levetiracetam binding site or LBS : Noyer *et al.*, Euro. J. Pharmacol. 286:137-146.

15 (1995); Gillard *et al.* 2003)). However, [<sup>3</sup>H]LEV displayed only micromolar affinity for this site, making it unsuitable for in depth characterization. This example describes the binding properties of [<sup>3</sup>H]ucb 30889, (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide, an analogue of levetiracetam. Binding experiments were conducted on crude rat brain membranes at 4°C as described in Noyer *et al.* (Euro. J. Pharmacol. 286:137-146 (1995)).

20 Incubation time for equilibrium studies was 120 min. For kinetic and competition studies, [<sup>3</sup>H]ucb 30889 (30 Ci / mmol) was used at a concentration of 1.3 nM in 0.5 ml of a Tris-HCl (pH 7.4) buffer containing 2 mM Mg<sup>2+</sup>. Localization of the LBS in brain substructures was assessed by autoradiography on 25 µm thick slices incubated under similar conditions. Slides were then washed twice for 10 min at 4°C in 50 mM Tris-HCl (pH 7.4) containing 0.5%  
25 BSA, dried and exposed for 3 weeks to [<sup>3</sup>H]Hyperfilm at -20°C. Non-specific binding (NSB) was determined by the inclusion of 1 mM LEV during the incubation period.

Figure 1 shows that [<sup>3</sup>H]ucb 30889 binds reversibly to LBS in rat brain cortex. Binding kinetics were biphasic: half-times for association and dissociation were respectively, 3 ± 2 min and 4 ± 1 min for the fast component (25 to 50 % of the sites), and 47 ± 13 min and 30 61 ± 15 min for the slow component. At 25°C, kinetics increased dramatically and only one component remained.

Figure 2 shows that the saturation binding curves of [<sup>3</sup>H]ucb 30889 were compatible with the labeling of a homogeneous population of binding sites.  $K_D$  and  $B_{max}$  were respectively  $42 \pm 10$  nM and  $5054 \pm 704$  fmol / mg protein. The  $B_{max}$  being similar to the value estimated using [<sup>3</sup>H]levetiracetam as radioligand in similar membrane preparations (4718  $\pm$  413 fmol / mg protein).

Specific binding could not be detected in the peripheral tissues examined (Figure 3). The limit of detection under the experimental conditions (150  $\mu$ g of protein / assay and 1.3 nM of radioligand) was a  $B_{max}$  of 200 fmol / mg protein. This suggests that there are at least 25 times more binding sites in the cerebral cortex compared to the periphery.

Competition binding curves showed that ucb 30889 binds to LBS with about 10 fold higher affinity than LEV (Figure 4). The  $pKi$  of ucb 30889 ( $7.1 \pm 0.2$ ) agrees well with the  $K_D$  of [<sup>3</sup>H]ucb 30889 as determined by the saturation binding curve (Figure 2).  $pIC_{50}$  values for a variety of levetiracetam analogues and other compounds known to interact with the LBS, such as pentylenetetrazol or bemegride (Noyer *et al.*, 1995), were identical whether obtained with [<sup>3</sup>H]ucb 30889 or [<sup>3</sup>H]levetiracetam (Figure 5).

Rat brain sections incubated with [<sup>3</sup>H]ucb 30889 (Figure 6) show that LBS labeled by [<sup>3</sup>H]ucb 30889 are diffusely localized throughout the brain and that this binding can be inhibited by levetiracetam at concentrations equivalent to those observed in *in vitro* binding (Figure 4).

This example demonstrates through competition binding studies and tissue distribution that ucb 30889 and LEV are both labeling the same sites, namely the LBS which is localized throughout the central nervous system. Compared to LEV, ucb 30889 binds to the LBS with 10 fold higher affinity and with a very low non specific binding. These criteria along with suitable binding kinetics at 4°C made it possible to use this radioligand to perform autoradiography binding studies on brain slices (Figure 6) and to show the anatomical distribution of LBS in rat brain.

#### Example 2. Cellular and Subcellular Distribution of the LBS

To identify and characterize the LBS *in situ*, [<sup>3</sup>H]ucb 30889 was used to map the LBS within the brain and to study both its cellular and subcellular distribution. For rat brain autoradiography, 25  $\mu$ m slices were incubated with 1.3 nM [<sup>3</sup>H]ucb 30889 for 120 min at 4

°C in 50 mM Tris-HCl buffer (pH 7.4). Binding assays with rat brain membranes and various neuronal cell lines were performed under similar conditions. Non-specific binding was determined by the inclusion of 1 mM levetiracetam in the assay. For photolabeling, membranes were incubated with 40 nM [<sup>3</sup>H]ucb 30889 for 120 min at 4°C in the same buffer, 5 followed by irradiation with UV-light for 30 min (Fuks *et al.*, Eur. J. Pharmacol. 478:11-19 (2003)).

For rat brain autoradiography, 25 µm slices were incubated with 1.3 nM [<sup>3</sup>H]ucb 30889 for 120 min at 4 °C in 50 mM Tris-HCl buffer (pH 7.4). Figure 7 shows that ucb 30889 binding sites are heterogeneously distributed in the rat brain. While there is no 10 apparent binding in the white matter there is a high level of binding in the dentate gyrus, the superior colliculus, several thalamic nuclei and in the molecular layer of the cerebellum. Binding is less pronounced in the cerebral cortex, the hypothalamus and the striatum. Abbreviations: cc, corpus callosum; Aca, anterio commissure; ic, internal capsule; Mtg, 15 mamillotegmental tractus; Mt, mammillothalamic tractus; ML, molecular layer; Hi, hippocampus; DG, dentate gyrus; sc, superior colliculus; CG, central grey; Pu, caudate putamen; Pv, paraventricular nucleus; MG, geniculate nuclei; Po hy, posterior hypothalamic areas; Hb, habenula; Pi, piriform cortex.

[<sup>3</sup>H]ucb 30889 binding in cerebellar granule neurons and PC12 cells showed high levels of specific binding (Table 1). The Kd being similar to the value measured in rat 20 cerebral cortex (42 nM; see Example 1). The same specific binding site could not be detected in primary astrocytes and in a range of CNS-related cell lines and non neuronal cell lines. Abbreviation: nd, not detected.

TABLE 1

Density and affinity of [<sup>3</sup>H]ucb 30889  
binding in various cell types

	Cell type	B <sub>max</sub>	Kd
5	Rat cerebellar granule neurons	0.7 pmol/mg protein	59 nM
	Mouse cortical neurons	1.4 pmol/mg protein	34 nM
	Mouse cortical astrocytes	nd	
	PC12	1.4 pmol/mg	40nM
	SK-N-SH	nd	nd
	NG108-15	nd	nd
	N1E-115	nd	nd
10	HCN-1a	nd	nd
	CHO-K1	nd	nd
	COS-7	nd	nd

Rat brain membranes were separated by differential centrifugation (Figure 8).

Binding to LBS (8A), muscarinic (8B), NMDA (8C) and peripheral benzodiazepine (8D) receptors was determined using [<sup>3</sup>H]ucb 30889, [<sup>3</sup>H]NMS, [<sup>3</sup>H]MK801 or [<sup>3</sup>H]PK11195, respectively. This study shows that the levetiracetam binding site is present in crude synaptosomes (P2), microsomal membranes (P3) and is enriched in synaptic vesicles (LP2). In contrast, the other studied receptors are not more abundant in LP2 compared to P2 or P3. P1 is a low speed pellet containing nuclei and large debris.

A fractionation onto a sucrose gradient was used to isolate the subcellular compartments from crude synaptosomes. The LBS was found in purified synaptic membranes but was not present in the 1.2 M sucrose pellet containing the purified mitochondrial fraction (Figure 9). As a control for the purity of the subcellular fractions, the distribution of the muscarinic and the peripheral benzodiazepine receptors was also analyzed. Data are expressed as percentage of the total specific binding.

Crude synaptosomes (P2 fraction) were preincubated with 40 nM [<sup>3</sup>H]ucb 30889, then

irradiated with UV light and washed. At 0 min 1 mM levetiracetam was added and aliquots were counted at the indicated times (Figure 10A). Nonspecific binding (open symbol) was determined using 1 mM levetiracetam. Figure 10B shows the same experiment, but performed in the absence of UV light irradiation. These results indicate that during UV

5 irradiation the radioligand inserts covalently in the binding domain of the LBS.

Photoaffinity labeling was performed in the absence or in the presence of 1 mM levetiracetam. The proteins were resolved by SDS-PAGE using an acrylamide concentration of 7.5 % (w/w) and the radioactivity was assessed in each slice of the gel. The major site of incorporation occurs at a molecular weight of 93,000 (Figure 11) (Fuks *et al.*, 2003)

10 In this example it is shown that the [<sup>3</sup>H]ucb 30889 binding site in rat brain has a unique profile of distribution and does not appear to correlate with any specific neurotransmitter system that is typically associated with epilepsy. This novel binding site is restricted to neuronal cell types and several brain areas. This novel radioligand can be used as a photoaffinity label and binds covalently to a membrane protein of high molecular weight

15 which is mainly located in synaptic vesicles.

### Example 3. The LBS is on SV2A

In this example, the biochemical characterization of LBS in rat brain led to studies to identify potential candidate LBS proteins for cloning and binding characterization. Based on 20 the integral membrane nature of the protein, brain specific expression, apparent size, and synaptic vesicle localization, the SV2 protein family was analyzed as a candidate for localization of the LBS. Accordingly, SV2 proteins were cloned and assayed for binding of LBS ligands.

25 **Materials:** Levetiracetam and derivatives were synthesized at UCB Pharma (Braine-l'Alleud, Belgium). [<sup>3</sup>H]ucb 30889, (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide (32 Ci/mmol), was custom labelled by Amersham Biosciences (Roosendaal, The Netherlands). The monoclonal antibody against SV2 proteins developed by Buckley and Kelly (Buckley *et al.*, *J. Cell. Biol.*, 100, 1284-94 (1985)) was obtained from the 30 Developmental Studies Hybridoma Bank developed under the auspices of the NICHD and maintained by The University of Iowa, Department of Biological Sciences, Iowa City, IA

52242. This antibody is cross-reactive against all three SV2 isoforms, SV2A, SV2B, and SV2C.

*Wild-type and Knockout Mouse Binding Experiments*

SV2A knockout mice have been previously reported (Crowder *et al.* Proc. Natl. Acad.

5 Sci. U.S.A. 96, 15268-73 (1999)). The generation of SV2B knockouts will be reported elsewhere. SV2B knockouts were bred with animals heterozygous for the SV2A gene disruption to produce SV2A+-SV2B-/ breeders which were used to generate SV2A/B knockouts. Wild type C57-Bl6 and SV2 KO mouse brain membranes were prepared for binding assays and the binding reaction was performed as described previously with slight  
10 modifications (Gillard *et al.*, Eur. J. Pharmacol. In Press (2003)). Frozen whole brains were homogenized (10 % w/v) in 20 mM Tris-HCl buffer (pH 7.4) containing 250 mM of sucrose (buffer A). The homogenates were spun at 30,000 x g at 4°C for 15 min and the pellets resuspended in the same buffer. After incubation at 37°C for 15 min, the membranes were washed 2 times using the same centrifugation protocol. The final pellets were resuspended in  
15 buffer A and stored in liquid nitrogen. Thawed brain membrane proteins (0.1 mg/assay) were incubated 120 min at 4°C in 0.5 ml of a 50 mM Tris-HCl buffer (pH 7.4) containing 2 mM MgCl<sub>2</sub>, and [<sup>3</sup>H]ucb 30889 (1.8 nM). At the end of the incubation period, the membrane-bound radioligand was recovered by rapid filtration through GF/C glass fiber filters pre-soaked in 0.1% polyethyleneimine. The membranes were washed with 8 ml of ice-cold Tris  
20 buffer (pH 7.4). The total filtration procedure did not exceed 10 s per sample. The filters were dried and the radioactivity determined by liquid scintillation. pIC<sub>50</sub>s determination was performed by computerized non-linear curve fitting methods (Graphpad Prism<sup>®</sup> software, San Diego, CA).

For Western blot experiments, aliquots of brain homogenates from the wildtype and

25 knockout animals were extracted at room temperature with SDS-PAGE sample buffer containing BME. Equivalent amounts of each sample (approx. 10µg total protein) were loaded on a 4-12% Tris-Glycine NOVEX gradient gel (Invitrogen Life Sciences) and separated. After transfer to a nitrocellulose membrane and blocking, the blot was probed with a monoclonal cross-reactive to all SV2 proteins (Buckley *et al.*, J. Cell. Biol., 100, 1284-  
30 94 (1985)), and an HRP-anti-mouse secondary antibody was used to label the primary. The

blot was developed with luminescent horseradish peroxidase reagents and photographed.

*Binding Experiments with [<sup>3</sup>H]ucb 30889 against heterologously expressed hSV2A*

For binding experiments on confluent, transfected cells (Figure 17), cells in 24 well plates were slowly cooled to 4°C and rinsed once with cold phosphate-buffered saline (PBS). PBS was aspirated and binding reagents were added in PBS. In binding experiments, [<sup>3</sup>H]ucb 30889 was added to all wells at 1.8 nM, in the presence or absence of differing amounts of unlabelled inhibitors. The cells were incubated at 4°C for 2h and the assay was terminated by rinsing the cells 3x rapidly with ice-cold PBS. After a final aspiration, 200 $\mu$ l of 0.1N NaOH was added to lyse the cells, and the samples were counted in scintillation fluid on a beta counter.

For binding experiments on previously frozen transfected COS-7 cells (Figure 18), 2 to 3 $\times$ 10<sup>4</sup> cells were incubated 120 min at 4°C in 0.2 ml of a RPMI-HEPES 25 mM solution containing [<sup>3</sup>H]ucb 30889 (1.8 nM) and increasing concentrations of unlabelled competing drugs. The termination of the binding reaction by filtration and radioactivity counting was performed as described above.

*Audiogenic Seizure Mouse Model*

Anti-seizure activity of LEV and analogues were assessed in sound-susceptible mice by exposing the mice to acoustic stimuli of 90-db, 10 to 20-kHz for 30sec, 60 min following intraperitoneal pretreatment. The reported ED<sub>50</sub> values were obtained from testing of 4 to 8 groups (n=10) administered different doses and reflect the potency of the compounds for inhibiting clonic convulsions.

Human SV2A was cloned from a human fetal brain cDNA library as a 3609 bp PCR product comprising the coding region and significant flanking regions from the transcript. Using a vector containing the SV2A coding region plus significant flanking DNA as a source, the coding region was PCR amplified without the flanking regions. This product was cloned into a GATEWAY (Invitrogen) donor vector for ease of subcloning. Only the use of a cloning vector with strong transcription stop sites directly upstream of the cloning site resulted in successful cloning of coding-region only SV2A cDNA. This suggests that this product may be toxic to *E. coli*, even in small amounts. Sequencing of the final pDONR GATEWAY SV2A clone showed that it had 2 mutations: one silent, and one a Leu-to-Pro

mutation. The non-silent mutation was corrected and sequencing confirmed that the correct, full length human SV2A coding sequence was cloned.

The human SV2A coding region was transferred from the pDONR GATEWAY cloning vector to a pDEST 12.2 Gateway expression vector. This vector has a CMV promoter driving the introduced gene, and an SV40 ori, which allows very high levels of replication in the COS-7 cell line, which contains the large T antigen. In addition, the human SV2A coding region was transferred into a pDEST 40 Gateway expression vector. This vector is very similar to the 12.2 vector above, with a CMV promoter driving expression of hSV2A, and an SV40 ori, and a Neomycin resistance gene.

Initial tests of SV2A expression using the pDEST 12.2 vector was performed in the COS-7 cell line, which had previously been demonstrated successful expression of SV2 proteins. The COS-7 cell line was tested for  $^3$ H-30889 binding, with no binding above background observed, and thus no significant, measurable presence of the Levetiracetam binding site (LBS). In addition, a PC12 cell line subclone, PC12a, which is low in LBS, was used to establish a pool of PC12 cells expressing hSV2A under stable antibiotic selection.

Lipofectamine 2000 (Invitrogen) transfection reagent was used to transfet DNA into 90% confluent COS-7 cells. Also, the same reagent was used to transfet the hSV2A containing vector into the PC12a cell line, and selecting for antibiotic resistance. Anti-SV2A polyclonal antibody (CalBiochem) was used to test for expression in either transfected COS-7 cells, or transfected PC12a cells, of the SV2A product. Lysates of the COS-7 cells were collected at 18 hrs after transfection on an SDS-PAGE gel, transferred to a membrane, and probed with a polyclonal antibody against SV2A, in comparison to crude rat brain membranes (Figure 12A). Also shown are lysates from a non-transfected COS-7 cells, non-transfected PC12a cells (low in LBS), PC12bs cells (high in LBS), or PC12a cells transfected with hSV2A (Figure 12B). No labeling of protein bands is observed in the untransfected COS-7 control, while the transfected COS-7 cells show multiple bands, with most density in the range of 80-120 kD, perhaps due to multiple glycosylation states of the expressed protein. In addition, SV2A immunoreactivity is present in the PC12bs and PC12a/hSV2A samples, but largely absent in the low LBS PC12a cells (Figure 12B).

In a binding experiment, specific binding was measured of  $[^3$ H]ucb 30889 to COS-7 cells that have either been transfected with SV2A-12.2, or as controls, a  $\beta$ -gal expressing

vector, or cells that have not been transfected (Figure 13). Triplicate wells of a 24-well plate were incubated with either 1 nM [<sup>3</sup>H]ucb 30889 (labeled "Hot"), or [<sup>3</sup>H]ucb 30889 plus an excess of cold Levetiracetam (50  $\mu$ M) (labeled "Hot + Cold"). The cells were incubated at 4 °C for 2 hours, and then washed rapidly with ice-cold PBS. The cells were lysed on the plate, 5 transferred to scintillation vials with scintillation fluid and counted for <sup>3</sup>H decay emission. These results show that COS-7 cells transfected with SV2A have acquired the capability to specifically bind [<sup>3</sup>H]ucb 30889. In identical intact cell binding experiments using PC12bs cells, known to express the LBS, a 1.5 to 2-fold difference in CPM between the 'hot' and 'hot+cold' samples is typically seen, as compared to the 5-fold difference seen here.

10 Further studies characterized the binding of [<sup>3</sup>H]ucb 30889 to SV2A expressed in COS-7 cells in more detail. COS-7 cells were transfected in a 24-well plate and assayed for binding as above. A series of concentrations of either Levetiracetam or cold 30889 were added in order to generate IC<sub>50</sub>s for these compounds against SV2A expressed in COS-7 cells (Figure 14). These results indicate that SV2A is functionally equivalent with the binding site 15 for Levetiracetam that has been observed in rat brain and PC12 subclones. The correlation between LBS binding affinity and the anti-seizure properties of Levetiracetam and its analogues, taken together with the preceding observation, provide support that the synaptic vesicle protein SV2A is not only the native binding site for the anti-epileptic compound Levetiracetam, but suggests a link between the function and modulation of the synaptic 20 vesicles by Levetiracetam and its anticonvulsant properties.

In a separate experiment, heterologous expression experiments were performed to confirm that SV2A alone is solely responsible for the brain binding of LEV. Human SV2A was transiently expressed in the COS-7 cell line, as verified by Western analysis (data not shown), and observed binding to [<sup>3</sup>H]ucb 30889 that is displaced by excess LEV (Figure 25 17A). No binding under identical conditions to either untransfected COS-7 cells, or COS-7 cells transfected with a vector encoding  $\beta$ -galactosidase. In experiments testing the ability of unlabeled compounds to displace [<sup>3</sup>H]ucb 30889 from hSV2A expressed in COS-7 cells, the affinities of ucb 30889, LEV, and LEV's enantiomer, ucb L060, show the same rank order, and similar values (Figure 17B), to those previously reported in studies with rat brain ((Noyer 30 *et al.*, Eur. J. Pharmacol. 286, 137-146 (1995); Gillard *et al.*, 2003). Critically, ucb L060 binds with significantly less affinity to hSV2A than does LEV, which is a key characteristic

of the binding site in brain (Noyer *et al.*, Eur. J. Pharmacol. 286, 137-146 (1995); Gillard *et al.*, 2003) In addition, the binding of [<sup>3</sup>H]ucb 30889 against both hSV2B and hSV2C expressed in the transient COS-7 system were tested. The results indicate no binding above background (data not shown), consistent with the results from knockout mouse binding studies.

5        Testing the binding of LEV and several analogs to hSV2A expressed in COS-7, revealed that pIC<sub>50</sub>s are highly correlated ( $r^2=0.98$ ) with the values obtained in mouse brain (Figure 18A) and rat brain extracts (data not shown). There was also a clear correlation between the affinities of these compounds for hSV2A in COS-7 and the potency of their antiseizure protection in the mouse audiogenic model of epilepsy ( $r^2=0.84$ ) (Figure 18B).

10      This data is consistent with a previous report of a correlation between binding of LEV analogs in rat brain and potency in the same model (Noyer *et al.*, Eur. J. Pharmacol. 286, 137-146 (1995)). The binding of other AEDs, including valproate, carbamazepine, phenytoin, ethosuximide, felbamate, gabapentin, tiagabine, vigabatrin and zonisamide was also investigated. None of the AEDs at concentrations up to 100  $\mu$ M, competed with [<sup>3</sup>H]ucb

15      30889 for binding to SV2A (data not shown). This confirms previous binding studies of AEDs against the LEV binding site in rat brain (Noyer *et al.*, Eur. J. Pharmacol. 286, 137-146 (1995); Gillard *et al.*, Eur. J. Pharmacol. 2003)).

**Example 4. Assays for Compounds Which Modulate Neurological Disorders,**

20      **Endocrinopathy and Hormonal Diseases**

In order to identify compounds or agents which modulate neurological disorders associated with synaptic function and endocrinological disorders, studies were undertaken to identify additional compounds which compete with LEV and ucb 30889 for binding to the LBS of a SV2 protein.

25      SV2A transfected COS-7 cells as disclosed in Example 3 are exposed to a potential binding partner or agent. Control cells are exposed to vehicle only, or are exposed to unlabeled ucb 30889 or LEV. Following this exposure, the cells are then incubated with [<sup>3</sup>H]ucb 30889, as in Example 3, cells are incubated at 4 °C for 2 hours, and then washed rapidly with ice-cold PBS. The cells are lysed, transferred to scintillation vials with

30      scintillation fluid and counted for <sup>3</sup>H decay emission.

Compounds which are found to compete with ucb 30889 for binding to the LBS are

subject to further analysis for the ability to modulate seizures in audiogenic-susceptible mice. Audiogenic-susceptible mice are administered an amount of the compound which is comparable to an effective amount of LEV. As a control, identical audiogenic-susceptible mice are administered an effective amount of LEV, or a compound which does not modulate 5 seizures, such as piracetam.

**Example 5. Biotinylated Ligands as Tools to Screen Chemical Libraries and Characterize the SV2 Proteins**

The present invention discloses a method of using novel biotinylated ligands as tools to 10 screen chemical libraries and characterize SV2 proteins. The present invention provides nonradioactive-labelled SV2A/LBS ligands containing a biotin tag for screening purposes with no radioactive waste and higher throughput. The present invention also provides a photoactivable version for labelling and SV2A/LBS detection in biological samples.

In this example, the binding of ucb-101282-1 to SV2A/LBS was characterized in rat 15 brain membranes. This molecule is a biotinylated derivative of ucb 30889 (Figure 19). This ligand had a pKi of 6.3 (n=2) in rat brain membranes which was equivalent to the affinity reported for L059 (Figure 20). This ligand was also designed to cross-link the biotin tag to the LBS/SV2A with an azidophenyl motif capable of forming a covalent complex with the protein upon UV light irradiation.

20

**Example 6. Method for Solubilizing SV2A and Affinity Purification**

The present invention discloses a method of solubilizing SV2A and affinity 25 purification. The method comprises solubilizing SV2A/LBS proteins which includes treating the membrane with a detergent. The method maintains the activity of the membrane proteins after solubilization as evaluated in binding assays and protein-protein interaction studies.

*Preparation of Soluble SV2A and Quantitation by Binding Assay*

The rat brain membranes were diluted in a solubilization buffer (Tris-HCl 20 mM pH 7.4, 0.25 M sucrose, protease inhibitors Complete Roche) containing n-dodecyl- $\beta$ -D-30 maltoside 15 mM and incubated for two hours at 4°C. Subsequently, the solution was centrifuged at 4°C for one hour at 100,000 g. The soluble SV2A was found in the

supernatant as detected by western blot using anti-SV2A antibodies (Figure 21A). The supernatants were incubated with [<sup>3</sup>H]ucb 30889 as described. Binding experiments indicated that the specific binding is due to a soluble form of SV2A. In order to detect the specificity of the SV2A binding, the ability of levetiracetam and ucb 30889 to specifically bind to the soluble SV2A was examined. The affinities of the molecules were equivalent to that exhibited by ligands to the native membrane (Figure 21B). Scatchard analysis indicates that the  $K_D$  for [<sup>3</sup>H]ucb 30889 for to the SV2A in native membrane is 30nM, while that for the soluble protein is 82 nM (Figure 21C). Thus, the binding properties of the soluble SV2A are similar to the membrane-bound native form indicative that the soluble protein maintains its native structural conformation in n-dodecyl- $\beta$ -D-maltoside.

*Affinity Purification of the Soluble SV2A and Identification of Putative SV2A Partners*

Supernatants from solubilized membranes were incubated with anti-SV2A antibodies overnight at 4°C. The mixture was rotated with protein A-Sepharose beads for 1 hour at 4°C in Tris-HCl 20 mM pH 7.4, 0.25 M sucrose, protease inhibitors Complete (Roche). The resin was washed several times and the collected fractions contained immunopurified SV2A (Figure 22). As explained above, SV2A is maintained in its native conformation after solubilization in n-dodecyl- $\beta$ -D-maltoside. Therefore, since synaptotagmin is a well known partner of SV2A, the immunopurified fractions were tested to determine whether synaptotagmin was still associated to SV2A after the purification procedure. Western analysis of the immunopurified fractions confirmed the presence of synaptotagmin associated to soluble SV2A, while the isoform SV2B was not detected. Thus, the solubilization and purification procedure can be used to perform SV2A-protein interactions studies.

Although the present invention has been described in detail with reference to examples above, it is understood that various modifications can be made without departing from the spirit of the invention. Accordingly, the invention is limited only by the following claims. All cited patents, patent applications and publications referred to in this application are herein incorporated by reference in their entirety.

WHAT IS CLAIMED IS:

1. A method of treating a neurological disorder associated with synaptic vesicle function, endocrinopathy or hormonal diseases, comprising administering a compound or agent that modulates a function or activity of an SV2 protein.  
5
2. A method of claim 1, wherein the neurological disorder is selected from the group consisting of seizure, epilepsy, Parkinson's disease, Parkinson's dyskinesias, migraine, Alzheimer's disease, neuropathic pain, essential tremor, cognitive disorders, and movement disorders.  
10
3. A method of claim 1, wherein the compound or agent binds to the levetiracetam binding site of an SV2 protein.
- 15 4. A method of modulating at least one function or activity of a SV2 protein in a cell, comprising exposing the cell to a compound or agent that binds to the levetiracetam binding site of the SV2 protein.
- 20 5. A method of claim 4, wherein the compound or agent modulates the binding of levetiracetam to the levetiracetam binding site.
- 25 6. A method of discovering or modeling an interaction between an SV2 protein and a compound or agent selected from the group consisting of: levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site comprising:
  - a) contacting the SV2 protein with the compound or agent; and
  - b) measuring and analyzing the interaction of the SV2 protein with the compound or agent.
- 30 7. A method of claim 6 where the analysis is by proteolytic treatment of the SV2 proteins to observe a differential effect of binding of a ligand on proteolytic degradation.

8. A method of claim 6, wherein the analysis is by 3-dimensional modeling or other purely computational techniques.

5 9. A method of claim 8, wherein the 3-dimensional modeling is via nuclear magnetic resonance spectroscopy or X-ray crystallography.

10. A method of claim 6, wherein the analysis is by binding studies.

10 11. A method of any one of claims 6 or 10, wherein the SV2 protein is purified from natural sources

12. A method of claim 11 where the SV2 protein is purified from heterologously expressed protein driven from a cloned nucleotide inserted in an expression vector, in a  
15 eukaryotic or prokaryotic host.

13. A method of identifying a levetiracetam binding site within an SV2 protein comprising;

20 a) contacting a SV2 protein or fragment thereof with a compound or agent selected from the group consisting of levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site; and  
25 b) determining the binding of the compound or agent with the SV2 protein or fragment thereof.

14. A method of claim 13, wherein the SV2 protein or fragment thereof comprises at least one amino acid substitution, deletion or addition.

30 15. A method of claim 14, wherein the addition, deletion or substitution of amino acid residues removes at least one glycosylation sites.

---

16. A method of claim 15, wherein the removal of glycosylation sites is *via* site-directed mutagenesis.

5 17. A method of claim 13, wherein the SV2 protein is a fusion protein comprising at least one SV2 protein or fragment thereof and a fusion partner.

18. A method of claim 17, wherein the fusion partner is a fusion tag.

10 19. A method of claim 18, wherein the fusion tag is a poly-His tag or glutathione-S-transferase.

20. A method of assaying the interaction between SV2 protein and a second protein comprising;

15 a) expressing SV2 protein and the protein of interest in a cell;

b) exposing the cell to a compound or agent which binds to the levetiracetam binding site; and

c) determining the interaction between the SV2 protein and the protein of interest.

20 21. A method of claim 20, wherein the second protein is selected from the group consisting of: a cell membrane protein, a vesicle membrane protein, a cytoplasmic protein, a cytoskeletal protein, and an intracellular matrix protein.

25 22. A method of claim 20, wherein the protein of interest is synaptotagmin.

23. A method of claim 20, wherein the protein of interest is a member of the SNARE complex.

30 24. A method of claim 23, wherein the member of the SNARE complex is synaptic vesicle associated VAMP/synaptobrevin, syntaxin, or SNAP-25.

---

25. A method of claim 20, wherein the SV2 protein lacks at least one glycosylation site.

26. A method of identifying a compound or agent that modulates a neurological disorder  
5 associated with synaptic function, endocrinopathy or hormonal disease comprising;  
a) exposing a SV2 protein to the compound or agent; and  
b) determining whether the compound or agent modulates an activity of the SV2  
protein.

10 27. A method of any one of claim 3, 4, 5, 6, 20, or 26, wherein the compound or agent is  
levetiracetam or an analog or derivative thereof, or an anti-SV2 antibody or fragment  
thereof.

15 28. A method of any one of claims 13 or 27, wherein the compound or agent competes  
with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding  
site.

20 29. A method of any one of claims 13 or 27, wherein the compound or agent is an anti-  
SV2 antibody or fragment thereof.

30. A method of claim 29, wherein the anti-SV2 antibody or fragment thereof binds to the  
levetiracetam binding site of SV2 protein.

25 31. A method of claim 29, wherein the anti-SV2 antibody or fragment thereof is selected  
from the group consisting of a polyclonal antibody and a monoclonal antibody.

32. A method of claim 31, wherein the antibody fragment is selected from the group  
consisting of an Fab fragment, Fab' fragment, F(ab')<sub>2</sub> fragment and an scFv fragment.

30 33. A method of claim 31, wherein the monoclonal antibody is selected from the group  
consisting of a chimeric antibody, a humanized antibody, and a human antibody.

34. A method of identifying a cellular response to a compound or agent selected from the group consisting of levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site comprising:

- 5 a) exposing cells expressing an SV2 protein to the compound or agent; and
- b) analyzing a change in the expression of a nucleic acid or protein in the exposed cell.

10

35. A method of any one of claims 20 or 34, wherein the step of exposing the cell to a compound or agent which binds to the levetiracetam binding site is carried out under conditions with a divalent cation concentration selected from the group consisting of less than about 1  $\mu$ M, between about 1  $\mu$ M and about 1000  $\mu$ M, and at least about 1000  $\mu$ M.

15

36. An isolated nucleic acid molecule comprising the nucleic acid sequence of SEQ ID NO: 5 or the complement thereof.

37. An isolated polypeptide comprising an amino acid sequence encoded by the isolated 20 nucleic acid molecule of claim 123.

38. An isolated polypeptide of claim 124, comprising the amino acid sequence of SEQ ID NO: 6.

25 39. A method of claim 26, wherein the step of determining whether the compound or agent modulates an activity of the SV2 protein is selected from the group consisting of

- a) measuring transport of at least one monovalent cation or divalent cation across a membrane;
- 30 b) measuring SNARE complex formation;
- c) measuring  $\text{Ca}^{2+}$  channel formation or activity;
- d) measuring SV2 interaction with at least one other protein;

e) measuring transport of at least one substrate across a membrane; and,

f) measuring synaptic vesicle fusion, exocytosis, or synaptic vesicle recycling.

40. A method of claim 39, wherein the monovalent cation is selected from the group

5 consisting of H<sup>+</sup>, Cl<sup>-</sup>, Na<sup>+</sup> and K<sup>+</sup>.

41. A method of any one of claim 35 or 39, wherein the divalent cation is selected from the group consisting of Ca<sup>2+</sup>, Zn<sup>2+</sup>, Pb<sup>2+</sup>, Mg<sup>2+</sup>, Mn<sup>2+</sup>, Fe<sup>2+</sup> and Cu<sup>2+</sup>.

10 42. A method of claim 41, wherein the at least one divalent cation is Ca<sup>2+</sup>.

43. A method of claim 39, wherein the at least one other protein is synaptotagmin.

44. A method of claim 39, wherein the at least one other protein is laminin-1.

15

45. A method of claim 39 wherein the at least one substrate is selected from the group consisting of amines, acetylcholine, excitatory neurotransmitters, GABA, serotonin, glycine or other amino acids, sugars and organic ions.

20 46. A method of identifying a binding partner for a SV2 protein, comprising:

- a) exposing a SV2 protein or fragment to a potential binding partner;
- b) incubating the protein or fragment and potential binding partner with (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide; and
- c) determining if the binding of (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide to the protein is inhibited by the potential binding partner, thereby identifying binding partner for the protein.

25

47. A method of identifying a compound or agent useful for the treatment of a neurological or endocrinological disorder, comprising:

30 a) exposing a SV2 protein or fragment to the agent and levetiracetam or an analog or derivative thereof; and

b) determining if the binding of levetiracetam or an analog or derivative thereof to the protein is modulated by the agent, thereby identifying an agent useful for the treatment of a neurological disorder.

5 48. A method of claim 47, wherein the levetiracetam or an analog or derivative thereof is directly or indirectly labeled.

49. A method of claim 47, wherein the SV2 protein or fragment is incubated with the levetiracetam or an analog or derivative prior to the agent, after addition of the agent, or 10 concurrent with the agent.

50. A method of claim 47, wherein the SV2 protein or fragment is incubated with levetiracetam.

15 51. A method of claim 47, wherein the neurological disorder is selected from the group consisting of epilepsy; epileptogenesis; seizure disorders; convulsions; withdrawal seizures; neurological disorders; bipolar disorders; mania; depression; anxiety; migraine; neuralgia; trigeminal neuralgia; chronic pain conditions; neuropathic pain; anaesthesia-related hyperexcitability; cerebral ischemia; head trauma; myotonia; excitatory states provoked by 20 drug or alcohol abuse, dependence or withdrawal; stroke; myoclonus; essential tremor; tics; Tourette's syndrome; dyskinesia; spasticity; movement disorders; neonatal cerebral haemorrhage; amyotrophic lateral sclerosis; Parkinson's disease; Alzheimer's disease; a neurodegenerative disease; and dementia.

25 52. A pharmaceutical composition comprising a compound or agent as identified in the method of any one of claims 26 or 47 said compound being different from a compound as described in Fig. 15.

53. A method of treating a neurological or endocrinological disorder which comprises 30 administering to an individual in need of such treatment a compound or agent as identified in the method of any one of claims 26 or 47 said compound being different from a compound as

described in Fig. 15.

54. A method according to claim 53, wherein the neurological disorder is selected from the group consisting of epilepsy; epileptogenesis; seizure disorders; convulsions; withdrawal seizures; neurological disorders; bipolar disorders; mania; depression; anxiety; migraine; neuralgia; trigeminal neuralgia; chronic pain conditions; neuropathic pain; anaesthesia-related hyperexcitability; cerebral ischemia; head trauma; myotonia; excitatory states provoked by drug or alcohol abuse, dependence or withdrawal; stroke; myoclonus; essential tremor; tics; Tourette's syndrome; dyskinesia; spasticity; movement disorders; neonatal cerebral haemorrhage; amyotrophic lateral sclerosis; Parkinson's disease; Alzheimer's disease; a neurodegenerative disease; and dementia.

55. A method according to claim 53 wherein the endocrinological disorders is selected from the group consisting of endocrinopathies involving hypersecretion or hyposecretion of at least one hormone; gigantism; dwarfism; adrenal-medulla-related diseases; hypoglycemia; and circulation shock.

56. A method of any one of claims 1, 20, 26, 34, or 47, wherein the SV2 protein is SV2A.

20 57. A method of claim 56, wherein the SV2A protein comprises SEQ ID NO: 2.

58. A method of claim any one of claims 13, 27, or 47, wherein the analog or derivative of levetiracetam is (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide.

25 59. A method of claim 58, wherein the analog or derivative of levetiracetam is selected from the group consisting of N-alkylated 2-oxo-pyrrolidine derivatives, N-alkylated 2-oxo-piperidinyl derivatives, and N-alkylated 2-oxo-azepanyl derivatives.

60. A method of identifying an agent useful for the treatment of a neurological or 30 endocrinological disorder, comprising:

a) exposing a SV2 protein or fragment to the agent;

---

b) incubating the protein or fragment and agent with (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide; and

c) determining if the binding of (2S)-2-[4-(3-azidophenyl)-2-oxopyrrolidin-1-yl]butanamide to the protein is inhibited by the agent, thereby identifying binding partners for

5 the protein.

61. A method of discovering or modeling an interaction between an SV2 protein, or fragment or derivative thereof, and a compound or agent selected from the group consisting of: levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which

10 competes with levetiracetam or an analog or derivative thereof for binding to the levetiracetam binding site comprising:

a) creating a 3-dimensional model of the SV2 protein, or fragments thereof, via either biochemical, biophysical, purely computational techniques, or some combination of these; and

15 b) creating 3-dimensional model of one or a collection of potential ligands that might potentially bind the SV2 protein.

62. A method of claim 61, further comprising using purely computational techniques to dock the 3-dimensional model of SV2 proteins with the 3-dimensional models of potential

20 ligands.

63. A method of discovering or modeling an interaction between an SV2 protein and a compound or agent selected from the group consisting of: levetiracetam, an analog or derivative of levetiracetam, or a compound or agent which competes with levetiracetam or an

25 analog or derivative thereof for binding to the levetiracetam binding site comprising:

a) determining a biochemical, pharmacological, organismal, cellular or molecular effect of a potential CNS active molecule in a genetically wild-type animal or in molecules, cells or tissues derived from such animals; and

b) comparing the measured effect of that compound in an equivalent study in a

30 system with an SV2 protein knocked out or knocked down.

64. A method of isolating a functionally active membrane associated SV2 protein complex comprising:

- a) solubilizing tissues comprising the SV2 protein with a detergent; and
- b) isolating the SV2 protein complex.

5

65. A method of claim 64, wherein the method further comprises purifying the SV2 protein complex by immunoaffinity.

66. A method of claim 65, wherein the SV2 protein complex is further purified to obtain  
10 the SV2 protein.

67. A method of claim 64, wherein the detergent is n-dodecyl- $\beta$ -D-maltoside or derivatives or analogs thereof.

15 68. A method of claim 64, wherein the tissues are brain membranes.

69. A method of claim 64, further comprising identifying the molecule or molecules complexed to the SV2 protein.

20 70. A method of any one of claims 64 to 69, wherein the SV2 protein is SV2A protein, SV2B protein, or SV2C protein.

71. A purified SV2 protein complex obtained by the method of claim 64.

25 72. A purified SV2 protein complex of claim 71, wherein the SV2 protein is SV2A protein, SV2B protein, or SV2C protein.
